and marketing. Ethnography has remained popular in these fields, but the meaning of the method is contested. Ever more practitioners claim to offer 'ethnography' to businesses as a service, with ever widening conceptions of the craft. Some boutique firms offer consumer research services but do not believe anthropology is necessary or even desirable; perhaps anthropology is only a 'middleman' introducing extraneous interpretations, while the corporate clients desire the unvarnished consumer (Malefyt, 2009). Ethnography may mean no more than videotaping consumer behavior and/or using various brands of digital technology to facilitate customer self-documentation and transmission of recordings direct to corporate clients. Such 'technoethnography' could be faster and less expensive than anthropological ethnography or rapid ethnographic methods. As in an earlier era of industrialization, the skilled work of ethnography could be in jeopardy unless anthropologists are able to explain and/or enact its strategic significance with clients.

The Anthropology of Finance

Twenty-first-century society has fostered a new subfield of business anthropology, focused on the professional cultures and gendered landscapes of finance and their intersection with the larger society. The modern financial crisis was first reported in the *Financial Times* by anthropologist Gillian Tett (2009) who understood the role of exotic banking practices (e.g., derivatives). Recent ethnographies of financial professionals reunite anthropology with a century-long tradition of inquiry focused on social institutions – the shared rules, norms, and cognitive constructs that enable both continuity and resilience in complex societies. Anthropologists have been creative in approaches to understanding financial institutions, apprenticing to future traders as a means to discover the rules of market discipline in a technology-mediated environment (Caitlin Zaloom, 2006); learning how disbanded members of a Japanese securities firm apply the metaphor of arbitrage trading (which rests upon a very specific construction of time) to areas of life that fall outside the market (Hirokazu Miyazaki, 2003); accessing investment bankers' experiences with job loss to learn how they reproduce corporate downsizing as a result of their own embodied experiences (Karen Ho, 2009); and developing innovative methodologies to study the first generation of women on Wall Street and their navigation of the masculine world of finance through networking organizations dedicated to women's advancement (Melissa Fisher, 2012). Such studies have placed the anthropology of finance at the forefront of understanding the relationships among professional knowledge and expertise, technological change, and social institutions, and continue to suggest the potency of anthropology as a contributor to research on business and society.

Abstract

This article explores business education from its rather primitive beginnings to the complex topic it is today. It offers critical perspectives on business education and aims to not only inform but provoke thought and discussion. It starts with a brief historical overview of business education and moves to explore the links between business strategy and education. It considers the relevance and importance of technical versus personal development and the role of innovation and creativity in modern business settings. It then considers the questions: 'What type of people does modern business require?' and 'How are they going to be developed?' These are discussed in the context of leadership and leadership development. Finally, it raises issues about the future by considering the behaviors and practices of business and offers a perspective on the largely underdeveloped concept of 'knowledge productivity' within the construct of a corporate curriculum.

Introduction

This article considers the development of business education from its rather primitive beginnings to the relatively complex topic it is today. It offers critical perspectives on business education as it aims to not only inform but provoke thought and discussion – there are few right answers here!

Beginning with a brief historical overview of business education, it moves on to explore the links between business strategy and education. Then it considers the relevance and importance of technical versus personal development and then the role of innovation and creativity in modern business settings. It considers the questions: 'What type of people does modern business require?' and 'How are they going to be developed?' These are discussed in the context of leadership and leadership development.

Finally, it raises issues about the future in relation to the changing social circumstances brought about by the global economic crisis. It discusses the behaviors and practices of business and offers a perspective on the largely underdeveloped concept of 'knowledge productivity' within the construct of a corporate curriculum (Kessels, 2002).

Brief History of Business Education

> It is groups, not individuals, that adapt to their environments and this is the basis for the peculiar genius of the human species. We are a successful species because we cheat; we tell each other the answers
> Emler and Heather, 1980.

The above quotation, in a nutshell, says all there is to say about education! If we do not support each other to learn, we do not sustain (*see* Sustainable Lifestyles; Sustainable Practices; Sustainable Production and Consumption) or progress. From ancient Greek times, where the epic poem, The Odyssey, was written with a story line about the education and development of the young prince Telemachus through to medieval guilds whose specific purpose was for the development of skills (*see* Education: Skills Training), to modern times where education has become even more important as a driver to economic progress, business education has always had a function.

Business Education and Strategy

Why would any business be interested in educating its workforce?

One response may be found in the imperatives of business strategy (*see* Education, Economics of). Most businesses within capitalist economies are driven by profit. This may translate into developing market share or seeking that elusive 'competitive advantage.'

In recent history, competitive advantage seems to be sought through a range of business drivers. The late-1980s and early-1990s organizations sought competitive advantage through the superior quality of their products or services. This strategy led to great improvements in productivity, efficiency, and technological innovation and a demand for a highly skilled technical workforce able to be flexible and adaptable, to be innovative and self-sufficient.

A business faced the choice of developing its own people or buying in the skills needed. The second option, while attractive, was more difficult to achieve as the competition for skilled workers increased. This in turn put pressure on education systems. Paradoxically, some skilled workers started to become deskilled as a result of technology, as their traditional skills were replaced by automation.

In the UK during this period, the public sector also saw many changes. A restructuring of the National Health Service saw the notion of competition becoming a driver for efficiencies and cost savings, and the long tradition of cooperation within the Service was put under strain. The attitudes, skills, and knowledge needed to manage health care started to change, and this meant that large numbers of doctors sought business education.

Competitive advantage based on quality alone became difficult to sustain. The 'quality' race led to organizations discovering that much less divided them, and high-quality products with high-quality service at reduced cost became the entry point for business (Hamel and Prahalad, 1989, 1991).

There followed a search for new differentiating strategies. Businesses developed new customer-led strategies that required not only quality products and service but value for money and after-sales care. Slogans began to appear in organizational documents such as 'people mean business,' 'we are in it for

the long haul,' 'people are our most important asset,' and the concepts of strategic human resource development and team working evolved. This created 'people-led' strategies with organizations seeking competitive advantage through their people.

In business education terms, perhaps the most significant publication to appear during this period was Senge's *The Fifth Discipline: The Art and Practice of the Learning Organization* (1992). This was reviewed in 1997 in the Harvard Business Review as one of the seminal business works in the last 75 years – business education was on the map!

Research in this period, for example, Huselid (1995) and Patterson et al. (1998), explored the relationship between people development and business performance. These studies suggested that the relationship was positive – developed people contribute to business progress.

Some saw these events as managerial attempts to 'gloss' over the flaws in 'disorganized capitalism' (Lash and Urry, 1987). Later, others took a more generous view, as Kessels (1996) put it:

> …a far more cogent argument would be that organizations have a direct stake in the personal enrichment of employees because excellence on the job requires employees who are comfortable with their work and who have strong and stable personalities. Personal enrichment is thus less an employee privilege than a condition for good performance
>
> p. 4; *see* Metacognitive Development: Educational Implications

As we moved into the new millennium, businesses still searched for competitive advantage. The drivers of innovation and deregulation came on the agenda. Business was using its lobbying power to achieve changes in legislation on both sides of the Atlantic and it became more global and less interested in national boundaries. New markets were sought; new, cheaper centers for manufacturing were established. New distribution channels were developed and computerization dominated all aspects of business. These searches raised moral questions for business and notions such as 'corporate social responsibility' and 'ethical' developed. The British economist Will Hutton's views on deregulation in 1997 were almost prophetic:

> […] the operation of the unchecked market has an inherent tendency to produce unreasonable inequality, economic instability and immense concentrations of private, unaccountable power. To protect itself, society has to have countervailing powers built into the operation of the market, otherwise it cannot deliver its promise. Instead it collapses into licence masquerading as liberty, spivvery dressed up as risk-taking and exploitation in the guise of efficiency and flexibility.
>
> Hutton, 1997, p. 4

Deregulation happened and, arguably at least, this led to the global financial crisis of 2008. Here, 'innovations' in traditional business practices and changes in fundamental economic assumptions created unsustainable rapid growth and considerable individual wealth. In wider society, deregulation and uncontrolled globalization brought us corporatized 'neofeudalism' (Shearing, 2001) with localized 'fiefdoms' where rules are enforced and power bases established rather like the Baron of medieval times. The controllers of the 'fiefdoms' called for deregulation and freedom at the same time as imposing greater regulation and surveillance of those they controlled (Saul, 1997). The sad result is 'paternal authority' where the rights of individuals are sidelined "under the guise of business ethics…" (Schwartz, 2000, p. 175). This is both a leadership and ethical development issue.

So where are we now?

Tyson (2012) points out that in the "US jobs data reveals economy is bouncing back strongly from recession," but there is a serious mismatch between the needs of employers for technologically based skills and those available in the labor market. She argues that the "technological change is accelerating, fuelling demand for more skills at a time when the workforce's educational attainment levels have plateaued."

In the UK, employers face similar technical skill shortages. While UK organizations are recruiting more young people, the recruitment of more specialist employees is becoming more difficult.

Managerial- and professional-level staff are the most difficult to retain, and the methods most commonly practiced to encourage retention are providing business educational opportunities (CIPD, 2012).

Looking globally, "in the fifth year after the outbreak of the global financial crisis, global growth has decelerated and unemployment has started to increase again, leaving an accumulated total of some 197 million people without a job in 2012" (International Labour Organization (ILO), 2013, p. 2). Echoing the comments made by Tyson (2012), the findings of the ILO (2013) and the CIPD (2012) reports are clear that the "new jobs that become available often require competences that the unemployed do not possess" (ILO, 2013, p. 2).

There is now a highly competitive international market in high-level leadership and technical skills. Those who fail to keep ahead of these developments will lose their competitive advantage.

There are long-term cultural shifts in attitude and expectation. The global labor market has meant that people take a more strategic view of their career development and invest personal capital in their own business education. It is not surprising then that more and more employees negotiate opportunities for further training and professional development.

Organizations who respond to these expectations are likely to attract highly qualified staff and those that do not will disadvantage themselves.

It is vital that managers in organizations think strategically about the longer-term development of their human capital. Successful businesses will be those that take business education seriously.

To summarize, attitudes, skills, and knowledge change over time in relation to political, economic, and social changes. The role and purpose of business education changes with these shifts in thinking. Education remains an essential element in the political, social, and economic development – to quote a poster seen in a business recently: "If you think education is expensive, try ignorance!"

The Technical versus the Personal

Garvey (1997) noted that 'technical' skills and knowledge development dominate the training agenda. He also noted

that 'personal' skills development is largely underrepresented. However, he argues that 'personal' skills are essential management abilities that enable managers to lead teams effectively. It is here also that issues of power, status, and ethical problems can appear. So, while the technical development of people in business is essential, it is also important to develop managerial and leadership abilities. These may include communication skills, skills of influencing and persuading, time and project management, and in recent times, ethical awareness, coaching and mentoring, and critical and creative thinking.

Innovation and Creativity

The expectation of change is pervasive. The future is wide open, and new attitudes, skills, and knowledge are required. The new challenges on people require a new paradigm for business education.

As Garvey and Williamson (2002, p. 23) state, "It is rarely possible to predict from where the latest innovation will come. This means that the work organization needs to build potential or strategic capability within its people so that they are ready to adapt, react, respond and innovate (*see* Innovation and Employment). Chance favors the prepared mind and the preparation comes through people being open to rich learning opportunities so readily available in the work place…"

So, what type of person is needed in today's business world?

The Type of Person

A simple Web search for jobs anywhere in the world generates the same type of descriptions. Below is a composite list of the key attributes cited by potential employers in large, small, private, and public sector organizations around the world:

- Creative, analytical, problem solving, and technical skills (*see* Creativity Training)
- Excellent people skills, self-awareness
- Able to produce results to meet both customer and business needs
- Initiative and ability to learn and innovate
- Leadership abilities
- Personal values
- Honesty, positive self-esteem, and good personal presentation
- Capabilities to create, develop, and support a harmonious workplace
- Able to work with change
- Strong and stable personalities (*see* Personality Development and Temperament)
- Leadership

A challenging list indeed! How might these attributes be acquired, developed, and sustained?

One answer may be found in the quality of leadership within a business. Technical abilities remain essential for business progress, but the quality of leadership within a business determines its strategic progress.

Leadership development (*see* Leadership Education: Theory and Practice) is an important preoccupation of modern business. Many organizations develop competency frameworks against which they can assess readiness for leadership positions, design development interventions, develop talent, and plan succession routes. However, the issue of competencies within management development is controversial.

The argument against competencies is that they can lead to a 'training gap' orientation focusing on what people cannot do rather than on what they can.

Bolden and Gosling (2006, p. 148) suggest that competencies, being reductionist in nature, cannot prepare people for the complexities of a job role; they are not sensitive to specific situations, tasks, or individuals; they represent a view of past performance rather than acting as a predictor of future behavior; they tend to exclude subtle qualities, interactions, and situational factors, and they create a limited and mechanistic approach to learning. Garvey et al. (2009, p. 191) note "…when professionals are highly anxious – perhaps because of detailed surveillance and under strong resource pressure, then the delivery of competencies can degrade."

Taken together, these arguments suggest that a competency framework cannot prepare learners for either an uncertain future or changing circumstances – the very condition for which the above list of personal attributes seems to be designed! The implications here again for business education are considerable.

This seeming mismatch between the need for certain attitudes, skills, and behaviors, and the approach to acquiring them may be explained in the concept of 'mental models' (Senge, 1990).

Arguably, an overarching mental model in management is a positivistic orientation (Johnson and Duberley, 2000, p. 12). This mental model is based on the notion that 'good practice' in management is about cause-and-effect decisions, taking action, establishing objectives, and measuring their outcome. This discourse translates into organizational policies as the rational, pragmatic manager (Garvey and Williamson, 2002) attempts to control the system.

However, Barnett (1994, p. 37) states: "Society is more rational, but it is a rationality of a limited kind" and "genuinely interactive and collaborative forms of reasoning" are in danger of being driven out by this technical reasoning. When applied to business education, this approach tends to favor the prespecification of 'learning outcomes' or goals.

Prespecification for leadership development, for example, is common practice. While this does offer the possibility of accountability, measurement, and quality control to determine value for money, it also leads to reductionist thinking, creates unquestioning compliance, and stifles innovation and flexibility (Bernstein, 1971; Buckingham, 2001) – it limits 'collaborative reasoning.'

This mode of rationality cannot be adequate to guide learners if they are to be capable of flexibility, innovation, creativity, and improvisation (Habermas, 1974; Jessup, 1991; Barnett, 1994; Buckingham, 2001) – the widely agreed qualities required of the leaders of the future (Sosik and Megerian, 1999; Harris, 2004; Bolden and Gosling, 2006).

According to many writers (Polanyi, 1958; Argyris and Schon, 1981; Vygotsky, 1985; Bruner, 1990; Lave and Wenger, 1991) (*see* Vygotsky's Theory of Human Development and New Approaches to Education), learning is fundamentally

a social activity, which happens in a social context through dialogue. Therefore, leaders create the social context in which learning can take place – or not! As Daloz (1986, p. 68) states: "To understand human development, we must understand the environment's part, how it confirms us, contradicts us, and provides continuity."

The environment within a business makes it more or less possible for people to learn, develop, and perform. Traditionally, learning in business took place in classrooms with the education provided by an external agent. While there is still a place for this type of educational model and, indeed, many advantages, such as the introduction of new ideas and approaches, the potential for external critical comment, there is also a need for a more 'situated' (Lave and Wenger, 1991) or 'community of discovery' (Coffield and Williamson, 2011) approach.

'Situated learning' (*see* Situated Learning (Learning *In situ*)) is where "…learners inevitably participate in communities of practitioners and that the mastery of knowledge and skill requires newcomers to move toward full participation in the sociocultural processes of a community…" (Lave and Wenger, 1991, p. 29). It is an inevitable consequence of being at work, of doing the job!

The notion of 'situated learning' is not without its problems. It assumes that an individual learns through participating in a 'community of practice,' but groups can create power bases with those who are 'in' and those who are 'out.' This behavior is facilitated through the cultural rituals, language, assumptions, symbolic displays, and specific narratives at play within a particular community. With the idea of a 'community of practice' comes the risk of restricted openness or the limited introduction of new ideas and thus constrained innovation.

Community of Discovery – An Alternative View

Sir Isaac Newton observed, "I have seen further because I stood on the shoulders of giants." Most human discoveries have been collective social achievements, and here is the basis for the concept of a 'community of discovery.' Through inter- and multidisciplinary working, there is the potential for new thoughts to emerge as different perspectives engage with each other. If there is a sense among members of a group that new ideas are valued, acknowledged, and debated critically and openly, a 'community of discovery' becomes possible and new solutions to old problems may emerge.

Beyond the Organization

At a local level, organizations create environments to facilitate learning, but governments play their part by supporting business education. In recent times, the European Union memorandum on lifelong learning (2000), the G8 Group Cologne memorandum on lifelong learning (2000), many of Europe's national governments, Japan, Singapore, Australasia, and Taiwan are all committed to a public policy agenda that promotes lifelong learning in the workplace (see Field, 2000) for global competitiveness.

Business education is a global business!

Knowledge Productivity and the Corporate Curriculum

According to Garvey and Williamson (2002), all economies are knowledge economies and they always have been. Economic, social, and political progress has always been as a result of the application of new ideas and discoveries. In recent years, the notion of a 'knowledge economy' has acquired greater significance. Here, organizations need to develop their strategic capability and add value to their goods and services by the application of knowledge (*see* Intelligence, Prior Knowledge, and Learning). Kessels (2002) refers to this as 'knowledge productivity.'

We have Kessels to thank for developing the concept of the 'corporate curriculum.'

A curriculum is a program or course of study. All organizations have a curriculum whether planned, emergent, or chaotic! Kessels (1996) suggests that the idea of 'curriculum' is central to business education and is also is central to any credible account of organizational learning culture.

Bernstein (1971) suggested that to design any curriculum, it was important to consider the following questions:

1. What is valid knowledge in a specific context?
2. What is a valid way to deliver this knowledge?
3. How might this learning be evaluated?
4. How might this knowledge be realized in practice?

He suggested that there are two main elements to any curriculum – the 'formal' and the 'informal.'

In a 'formal' curriculum, the content is specific and prespecified. Knowledge is categorized by subject matter boundaries, and evaluation is dominant and therefore easier to deliver and assess. The content is largely controlled by the educator or teacher. The 'formal' curriculum tends to result in lower initiative, lower innovation, and lower creativity for the 'learner.'

In contrast, the 'informal' curriculum has less specific and more holistic content with loose subject matter boundaries. Rather than prespecifying the objectives of the learning, the 'informal' curriculum is driven by the prevailing circumstances or needs of the context – it is about relevance. Evaluation and assessment are related to the need that was being addressed and linked to utility and usefulness. This aligns it to Knowles' (1984) notion of andragogic adult learning, where the curriculum is

- based on the adult's need to know;
- experience-based;
- involving, shared, and participative;
- relevant and applied;
- problem-centered rather than content-oriented; and
- driven by the individual's internal motivations rather than external motivators (after Knowles, 1984).

The 'informal' curriculum fosters greater initiative and creativity in the learner.

The notion of curricula is deeply significant and has implications for organizations who take business education seriously. The 'formal' approach is advocated in many textbooks on the subject of training and development. The 'formal' position is often accompanied by the statement that business education needs to be strategically aligned, despite the fact that it is unlikely to deliver the innovation, flexibility, and

creativity needed for the knowledge economy (Broad and Newstrom, 1992).

However, the knowledge economy is dynamic – it is highly changeable and organizations need to be quick to anticipate and adapt. Therefore, working with a balance between the 'formal' and the 'informal' is more likely to build that all-important strategic capability for a capacity and potential for rapid change. A key question then is, 'What is best delivered formally and what is best delivered informally?'

The challenge is for managers to recognize that the workplace itself is a rich learning environment, which can provide the necessary stimulus and support for learning and knowledge generation. There is much evidence that this 'situated approach' (Lave and Wenger, 1991) offers a greater depth, understanding, and participation in learning for knowledge productivity.

Kessels (1996) embeds the metaphor of the 'rich landscape' of learning in his 'corporate curriculum' framework in the form of seven elements or 'learning functions':

- Expertise related to the core competence
- Problem solving
- Reflection and generation of new knowledge
- Communication
- Self-knowledge, metacognitions (*see* Teaching for Metacognition)
- Peace and stability
- Creative turmoil

The seven elements in the 'rich landscape' contain both 'formal' and 'informal' elements, and much depends on the type and purpose of a business as to the nature of the balance of the elements. In the 'rich landscape,' learning occurs through an active engagement and participation that encourages creativity, lateral thinking, and flexibility – the much-needed abilities of an employee of the future and the potential answer to the business education challenge in the twenty-first century.

Abstract

This article gives a brief overview of the history of business ethics starting with Aristotle. Different contemporary approaches to business ethics are surveyed, with an emphasis on continental European discussions. The article distinguishes between and focuses on the deliberative, the contractarian, and the contractualist approach to business ethics. The second part presents a short list of current topics and questions in business ethics.

Introduction

Business ethics is a discipline of ethics that is concerned with moral and ethical problems, norms, and values that arise in the area of business. As such, it requires interdisciplinary cooperation with other disciplines, in particular economics and the social sciences.

Business Ethics and Economic Ethics

In some parts of the non-English speaking world (e.g., Germany), business ethics is distinguished from economic ethics, in the same way that the discipline of economics is distinguished from business administration and management (cf. Luetge, 2012a). Business ethics, in this sense, would focus on ethical problems within and concerning mainly corporations and related organizations, whereas economic ethics would concentrate on larger scale ethical problems of entire economies. While this distinction can be useful in a number of contexts, it is, however, not common in most international debates. Therefore, this article uses the term 'business ethics' for both ethical enterprises.

History of Business Ethics

While the term business ethics only started to be used widely in the 1970s, the occupation with and the analysis of ethical problems in the area of business reaches back to Antiquity. The Greek philosopher Aristotle (384–322 BC) did not distinguish between ethics and economics as separate disciplines, but regarded them both as parts of 'praxis,' i.e., oriented toward action as their final goal (as opposed to theoretical disciplines concerned with truth, and 'poiesis' concerned with producing things) (cf. Aristotle, 2003). This mirrored the situation in the Greek city state (polis) in which ethical, economic, and political aspects were closely intertwined. Citizens could (to a much greater degree than in modern societies) directly observe and monitor the behavior of others. This situation was typical of premodern societies that can be characterized by face-to-face structures and interactions. Ethics, in this social context, was mostly concerned with recommending guidelines for individual behavior: the virtues. These virtues, in the premodern world, served directly both the interest of their bearers and the interest of the society as a whole.

In the premodern situation, the ethical challenge arose in particular due to the problem of justly sharing the fruits of a society that were mostly fixed in total: Premodern societies did not experience substantial and stable growth over longer periods of time (the Roman Empire being a possible exception). Therefore, individuals could only gain significantly at the expense of others. The result is a 'zero-sum society' (cf. McCloskey, 2006), which had significant implications for ethics. The successful fifteenth-century Florentine merchant Giovanni Rucellai stated it in this way: "by being rich, I make others (which I might not even know) poor" (Rucellai, 1772, written about 1450).

In order to remain stable, a zero-sum society needed an appropriate kind of ethics, i.e., an ethics that curbed excessive profits, greed – what Aristotle (2003) called 'pleonexia.' An ethics of temperance was the result, which called for the citizens to remain moderate, to be content with moderate gains and a 'just' price, or – in former times – to refrain from lending money at interest: Usury was condemned by a long tradition of theologians and philosophers ranging from Aristotle, the Bible, the Qur'an, Thomas Aquinas, and Martin Luther up to modern representatives (like S. Gesell).

The ethical view on the economy only started to change when the beginnings of significant economic growth became visible in the eighteenth century. Authors like B. Mandeville (1670–1733) began to reinterpret the role of self-interest, in particular by stating that actions motivated by self-interest have unintended consequences that may be beneficial for other citizens (cf. Mandeville, 1714/1924). The first systematic approach to the role of self-interest in modern economies was consequentially undertaken by Adam Smith (1723–90) in his two books *The Theory of Moral Sentiments* (1759/1976) and the *Wealth of Nations* (1776/1976). Both works are sometimes seen as being in opposition with one another, as the *Theory* recognizes the workings of sympathetic feelings in communities, while the *Wealth* focuses on the workings of self-interest in economies. However, both works do not necessarily contradict each other. Rather, they exhibit an important background problem of business ethics: the premodern vs. the modern society. Smith's *Theory* is concerned with how morality (sympathy) works in the premodern society, in small group settings. By contrast, the *Wealth* is concerned with the modern economy and society, where feelings of sympathy from premodern contexts cannot play a direct role in governing economies and societies. Rather, the

feelings can only become indirectly involved, via the structures, rules, and institutions of economics: This is the meaning of Adam Smith's doctrine, according to which mutually beneficent results of economic transactions cannot be derived directly from (in particular, 'moral') motivations of actors, but from their self-interest, which gets channeled in beneficent ways by the mechanisms of the economy: "It is not from the benevolence of the butcher the brewer, or the baker that we expect our dinner, but from their regard to their own interest. We address ourselves, not to their humanity, but to their self-love, and never talk to them of our own necessities, but of their advantages" (Smith, 1776/1976). This doctrine is highly relevant to business ethics in modern societies.

The opposite reaction to modern societies can be seen in the works of J.-J. Rousseau (1712–78), who espoused the idea of a static economy (Rousseau, 1755/1964), and K. Marx (1818–83). Marx actually welcomed the benefits capitalism brought to the workers, but he regarded it as a mere transitional phase on the way to the ultimate end of a communist society (cf. Marx and Engels, 1959).

The next important step was Max Weber's work on the supposed Protestant origins of capitalism (Weber, 2005, Original 1904/1905 and Weber, 2001, Original 1915–19), which contributed descriptively to business ethics. Weber's work focuses on the relation between religious convictions and the economic performance of a society.

Another historical development that is connected to Weber's ideas is the ideal of the 'honest businessman,' an ideal that has its European origins in both the Italian Renaissance as well as in the heyday of the Hanseatic League. This ideal consisted in ethical ideas about being honest and trustworthy, keeping promises, contributing to the community, and promoting not only cultural affairs but also practical abilities like speaking several languages and having organizational talent. The honest businessman is an ideal that originates from the practice of business, not from philosophical or economic theory. As such, it has been – and sometimes still is – present in Europe but evolved (in somewhat different ways) in other parts of the world as well, for example, in Japan (cf. Shibusawa, 1916).

Before dealing with the contemporary discussion of business ethics, its theological origins must be mentioned as well. In particular, both the Catholic and Protestant churches developed thoughts on business ethics (for other religious schools, see Luetge, 2013, Parts 11, 13, and 14). Several papal encyclicals had an important influence on ethical reflection in business ethics, such as 'Rerum Novarum' (1891, by Pope Leo XIII). Theologians like Heinrich Pesch (1854–1926) developed the doctrines of Catholic social teaching, which aimed at finding a third way between capitalism and socialism (Pesch, 1905ff.), and highlighted the importance of the principle of subsidiarity, according to which individuals were to resolve many social problems on their own, with the state stepping in only if individuals (or private law organizations) failed to resolve the problem. These ideas were developed further by others like Johannes Messner (1927) and Oswald von Nell-Breuning (1928).

The Protestant social teaching was developed by thinkers like Otto Baumgarten (1921) and Georg Wünsch (1927). Baumgarten aimed at combining capitalism with altruist motives in personal life. Wünsch, however, promoted a Christian socialism, which regarded capitalism only as a historical episode.

The contemporary debate on business ethics started in the United States during the 1970s, in particular as a reaction to scandals in business and the changed perception of the public. Before that, corporations had already used the term 'social responsibility' for different activities intended to be beneficial for society, albeit not in a systematic way. When business ethics entered the US scene, it made use of more systematic theoretical resources, namely, ethical theory and empirical case studies (cf. De George, 2006).

The Continental European discussion of business ethics, however, developed in quite a different way. It started, in the 1980s, with much more theoretically focused discussions between different schools, before it turned into a more empirically oriented debate as well. Although this had the disadvantage of being slightly more removed from the world of business originally, in the end a theoretical sophistication was achieved that took (and still takes) into account many theories from other disciplines, especially economics.

The following section discusses the main contemporary approaches to business ethics, both from the Anglo-American and the continental tradition.

Approaches to Business Ethics

While there is disagreement in a number of matters among the different approaches to business ethics, there is also consensus at least in some points: Nearly all approaches now accept (1) that ethics and business, morality and profit, or solidarity and efficiency hold no contradictions in principle and (2) that the institutions of the society have an important bearing on its ethics (although the exact extent of this is controversial).

Among the most prominent approaches to business ethics are the following: deliberative or discourse approaches, contractarianism, and the stakeholder approach. These are discussed in turn.

The Deliberative or Discourse Approach

Several approaches in business ethics rely on a foundation in the discourse ethics of Jürgen Habermas and Karl-Otto Apel. Some of them are Horst Steinmann, Peter Ulrich, and Andreas Scherer (cf. Steinmann and Scherer, 1998; Ulrich, 2008 (Original 1987); Scherer et al., 2006; and Palazzo and Scherer, 2006). Its theoretical core is the idea of an ideal discourse situation in which economic actors deliberate rationally on the foundations and rules of their society. This ideal discourse situation relies on a number of presuppositions, in particular, that coercion and force are not used in the discourse, as they belong to the domain of strategic rationality, which Habermas and Apel keep strictly separate from communicative rationality. Communicative rationality is regarded as having higher dignity, as (so Habermas insists) only the rational argument is to rule, against economic and administrative power.

Similarly, Peter Ulrich's 'integrative economic ethics' (Ulrich, 2008) tries to integrate economic rationality into a much broader framework of communicative rationality. In practice, this would mean that corporations are to include aims other than profit making into their goals – not as a better means to

profit making itself, but rather as an additional, second way of doing business. The individual actor is to reflect the rationality of his or her economic activities – and, when in doubt, give primacy to ethical considerations. Ulrich does not regard economic constraints as crucial, let alone decisive (that would be 'economism' in his eyes), but argues that it is in the hands of citizens to conduct a discourse on the foundations of their societal and economic basis – which will be constitutive to the economy and its processes.

Discourse ethics has spawned other approaches to business ethics as well, in particular the deliberative approach by Scherer et al. (2006). Deliberative democracy (cf. for example, Elster, 1998; Cohen, 1989; Aaken et al., 2004) is a theoretical approach that regards all actors (including corporations) as being subject to legitimation in societal deliberation. Deliberation is to prevent the dominance of economic rationality – and in that is directed against economics in general. However, economic actors like corporations are seen as engaging in public discourse for their own long-term success. Scherer regards it as the moral and political duty of corporations to develop a moral integrity based on their public deliberation, and thus actively engage in societal discourse on issues like human rights, working conditions, or environmental protection.

The dualist approach inherent here persists in other approaches to business ethics: ethics and economics, morality and business, or competition and solidarity are ultimately seen as opposing concepts.

Contractarian Approaches

Theories of the social contract have been among the most influential in political and social philosophy (cf. for example, Hobbes, 1651/1991; Hume, 1739–40/1978; and Rawls, 1971). Their theoretical core is the normative criterion of the actors' consent, which is usually only given if it serves the actor's self-interest.

In business ethics, this tradition has generated two different schools: contractarian and contractualist approaches, which can be distinguished in the following way (cf. Wempe, 2004): Contractualism assumes that contracting is subject to an internal morality, according to which contracts only work if the contracting parties have certain moral capabilities and can commit themselves to certain norms that are not ruled by self-interest alone. Contractarianism, on the other hand, does not regard an internal morality as a necessary condition of the contracting process or of its stability. The actors involved are seen as being self-interested in some way.

One approach to business ethics that makes use of social contract theory is the integrative social contracts theory (ISCT) of Donaldson and Dunfee (1995, 1999). Donaldson and Dunfee, whose theory can be classified as broadly contractualist, aim at developing a theory of business that starts from concrete problems of business. These concrete problems lie mainly in the nature of contracting, which, in the globalized world, is subject to many different standards and norms. ISCT is meant to explicitly allow for such a variety of norms – within limits, however. The contractarian idea is used to conceptualize both these intentions by distinguishing between macrosocial and microsocial contracts.

All (boundedly rational) human beings would consent to the macrosocial contract, which then regulates the process of norm finding on lower levels. This macro level, however, leaves a great degree of 'moral free space' to be filled by specific communities, corporations, or individuals: They agree upon microsocial contracts, within the macrosocial framework, which may comprise quite different norms and standards. To deal with the question whether any such norms and standards can be ethically acceptable, Donaldson and Dunfee introduce the concept of hypernorms. Hypernorms are meant to be universal, overarching ethical principles that "are sufficiently fundamental that they serve as a source of evaluation and criticism of community-generated norms, and may include not only rules specifying minimum behaviour, such as the rule against the killing of innocents, but imperfect duties such as virtue, beneficence and decency" (Donaldson and Dunfee, 1995, p. 96). Hypernorms express principles "so fundamental to human existence that one would expect them to be reflected in a convergence of religious, political and philosophical thought" (Donaldson and Dunfee, 1995, p. 96).

Having the contract paradigm in mind, it must be mentioned that ISCT's hypernorms are not subject to a contract themselves. Rather, they are seen as boundaries of the moral free space, together with the consent required from the members of the community and certain priority rules as rules of thumb for dealing with the inevitable norm conflicts between communities. To sum up, ISCT mainly tries to achieve a reconstruction of the (necessary) internal norms of contracting (cf. Wempe, 2009). It is therefore contractualist rather than contractarian.

The contractarian approach of order ethics ("Ordnungsethik"), by contrast, focuses on the order framework of a society as a means for implementing ethics within the economic world. It can be regarded as the complement of the German conception of 'Ordnungspolitik,' which stresses the importance of a regulatory framework ('Ordnung') for the economy. Order ethics is based on contractarianism: The members of a society agree on its rules, implicitly or explicitly. This agreement will only be given if the rules improve one's own position, at least in the long run, and if they improve it to a larger extent than the relevant alternatives.

Thus, the order framework of a society is regarded as a means for implementing ethics. Therefore, the discipline of economics takes a large space within this approach, as it has a long history of dealing with well-being, normativity, and norms under conditions of modern societies and economies. In the 'pure' tradition of ethics, implementation is most often conceptualized in terms of appealing to actors or their conscience.

By contrast, economics stresses the – not only economic but also ethical – importance of rules and incentives: Economics can teach ethically relevant lessons, one of which is the following.

The Role of Competition in Modern Societies

Order ethics emphasizes the special role competition plays in a modern society with market economy. Certainly, competition has many positive aspects (cf. Hayek, 1978). It fosters innovation and the spreading of new ideas, and it tends to erode positions of power (for example, those of former

monopolists). The negative aspects are the nonregard to justice, but (in a direct sense) only to efficiency, the role of luck (not only of merit), and the constant danger that morality gets crowded out when the incentives work against it.

Dilemma situations from game theory, in particular the prisoners' dilemma or the stag hunt game, model such situations in which morality gets crowded out if the incentives set by the rules, by the order framework, thwart the ethical aim (cf. Axelrod, 1984, for the systematic use of the stag hunt game cf. Binmore, 1994, 1998, 2005). In the classic model of the prisoners' dilemma, the prisoners cannot be expected to cooperate, because the conditions of the situation are set in a way so that cooperation is punished by defection on the part of the other player. The actors are permanently faced with the possibility of being 'exploited' by others if behaving cooperatively, and therefore they stop cooperating themselves preemptively. This leads to a situation where rational, self-interested actors end up with a result that leaves everybody worse and no one better off: Morality gets crowded out. However, rules are designed to prevent this from happening.

For example, corruption is seen as unethical, but some kinds of order frameworks (for example in Germany until 1998) allow for bribes to be deducted from tax, with the consequences of fostering unethical behavior. Order ethics aims at changing the order framework of a society rather than at appealing to moral behavior, by insisting that ethical behavior should be made possible by the rules and not get punished by (counterproductive) incentives.

The ethical consequence of this theory is to make markets more moral – not managers. This is the way Boatright (1999) put it, when he distinguished between a moral manager model and a moral market model. The first one focuses on appealing to individuals (managers, officials, trade unionists, etc.); the second one aims primarily at other aspects; in particular, this encompasses changing the institutional framework (thus indirectly inducing ethical behavior) and preventing rules and individuals' actions from getting into opposition with one another. Rules themselves are not sacrosanct, of course, but subject to meta-rules, in particular, constitutional rules. For these meta-rules, higher degrees of consent must be demanded (cf. Brennan and Buchanan, 1985).

Regarding the nature of rules, it should be stressed that order ethics does not deal only with those rules incorporated in the law, but with rules on other levels as well. This includes, in particular, agreements at branch level and also self-constraining actions of individual corporations. The underlying economic idea of mutual advantages, however, stays the same: to aim for a win–win situation.

Order ethics, as it becomes clear, does not equate altruism with moral behavior nor egoism with immoral behavior. The demarcation lies elsewhere, between unilaterally and mutually beneficial action: In order to act in an ethical way, actors should be pursuing their advantage in such a way that others benefit as well. This implies that there usually are different ways of pursuing one's own advantage, and the ethical challenge lies in finding new and better ways. What is needed here is some kind of 'moral imagination' (Werhane, 1999), which does not have to be detrimental to actors themselves, but rather give them advice on how to make profit in a mutually beneficial way.

Topics of Business Ethics

Apart from different theoretical approaches, the field of business ethics can be differentiated into a number of subtopics and subfields. The following are some of the most discussed:

1. Ethics of globalization: Business ethics in times of globalization presents specific ethical challenges. These are some of the central questions: How can the entire process of globalization be understood and analyzed from ethical points of view? How can different cultural, religious, or ideological differences be represented adequately? What responsibilities do multinational corporations (MNCs) have (cf., e.g., Homann et al., 2007)?
2. Criticism of capitalism: Already, but especially after the financial crisis of 2008–2009, fundamental criticism of the market economy has grown significantly. These are the important questions in this field of research: (How) Can capitalist societies be justified ethically or do we need to develop fundamental alternatives? Does capitalism have inherent ethical problems (cf., e.g., Chomsky, 1999)?
3. Sustainability: The concept of sustainability has become especially widely used, not only in ethics but also in other disciplines (e.g., terms like corporate sustainability, corporate sustainable management, and so on). From an ethical point of view, questions can be posed like: What counts as sustainable from an ethical perspective? What are ethical criteria for a sustainable economy? Do we need to develop sustainable lifestyles (cf., e.g., Marrewijk, 2003)?
4. Poverty: Poverty is still among the greatest both economic and ethical challenges in the world. What are the ethical consequences of poverty? Does the gap between the 'rich' and the 'poor' get larger or narrower? (How) Can inequalities be justified? Is extraordinarily high compensation justified (cf., e.g., Luetge, 2012b)? (How) Can instruments like microcredits be useful for ethical purposes (cf. Yunus, 2003)?
5. Unemployment: Unemployment, both an economic and an ethical problem, is abundant in many countries. Can a right to labor be justified? Is the concept of a basic (unconditional) income ethically desirable?
6. Ethics of financial markets: This kind of subfield has gained much ground since the financial crisis. These are some questions asked: Do financial markets need a special kind of ethics? Have bankers been too greedy and ruined the economy? Has the banking sector disentangled itself too far from the 'real' economy (cf. Boatright, 2007)?
7. Human rights and business ethics: The greatly increased role and power of MNCs have also increased the number of human rights problems for MNCs (cf. Bilchitz, 2013), such as: How should MNCs conduct business in countries with human resource (HR) deficits? How far can MNCs be required ethically to go to improve the local HR situation not only within their factories but also in society in general?
8. Management ethics: Many studies, articles, and concepts in business ethics deal with particular management instruments and how to make ethical use of them. These include (but are not limited to) the triple bottom line, ethics

committees, codes of ethics, ethics audits, whistle-blowing, and others (cf. Hosmer, 2008).

9. Corruption: The problem of corruption can be counted among the internationally most well-studied phenomena in business ethics. Some of the most pressing ethical questions posed are the following: How should corporations do business in highly corrupt countries? Can corporations be held responsible for corrupt practices that occur despite, and/or contrary to, company policy (cf. Lambsdorff, 2007)?
10. Diversity and gender: Many of the originally gender-focused discussions have now turned to the concept of diversity as an umbrella term encompassing many different aspects, including gender, ethnical background, religions and convictions, age diversity, sexual orientation, disabilities, and more. Most discussions center on the question of how MNUs can recognize and include all these aspects in their business (cf. Thompson, 2013; Luetge, 2013, Part 16).
11. Marketing ethics: What kinds of marketing can be regarded as ethically acceptable? Are there ethical limits to marketing strategies (cf. Murphy et al., 2004)?
12. Ethics of consumption: What responsibilities can be attributed to consumers (if any)? How can the concept of 'sustainable consumption' (cf. Seyfang and Elliott, 2009) be spelled out in detail?
13. Sponsoring: What kinds of sponsoring are ethically acceptable? What can sponsored organizations demand from their sponsors from an ethical point of view?
14. Entrepreneurship and ethics: This is a topic that has been neglected, which is, however, very important to the discussion of business ethics. What ethical responsibilities can be attributed to entrepreneurs? Do they (and if so, in what way) differ from the responsibilities of established corporations? How can social entrepreneurship be classified from an ethical standpoint?

Many of these topics lead into areas that have, since the 1990s, differentiated themselves from business ethics: corporate social responsibility, corporate citizenship, corporate social accounting, corporate governance, corporate sustainability management, and others.

In all these cases, the central question remains: How can ethics and profit and morality and self-interest be realized simultaneously, without one of the two getting suppressed by the other? This is the key challenge of business ethics.

Abstract

This article describes business history as an academic discipline before it sketches the main methods and approaches of the field. It also introduces the most important literature, the best journals, and the leading institutions of business history.

Business History

Strictly speaking, business history as the history of private and/or public corporations with specific legal structures must be distinguished from entrepreneurial history, the history of entrepreneurially active individuals. In the first instance, the concern is with the development of organizations in which questions of economic success loom paramount. In the second case, the object of study is a certain social type and/or personality as well as behavior, both inside and outside of the enterprise, including its social, cultural, or political implications. In practice, however, institutional and biographical approaches tend to overlap.

History of the Scholarly Discipline

Modern business and entrepreneurial history have two sources. First is the need of corporations and businesspeople for image cultivation and self-affirmation, which has led to the publication of numerous commissioned biographies and company histories as well as autobiographical accounts. The second major impetus behind the development of business history was the work of the German historical school of economics. This school questioned the explanatory power of classic liberalism and attempted to replace it with alternative concepts in which long-term perspectives as well as the entrepreneur played key roles in explaining economic growth. Of primary significance was the work of the scholars Gustav Schmoller, Werner Sombart, and Lujo Brentano.

Against this theoretical background, scholars around 1900 began to write academic business histories, thus establishing a counterweight to the celebratory accounts that banks and, later, large industrial firms produced. Both genres were reacting to the mounting criticism of the conduct and profits of big business. In this way, business history served, among other functions, to legitimize a rising social class that was rapidly acquiring both affluence and influence. In 1912, Richard Ehrenberg, whose history of the Siemens Brothers (1906) was one of the first company histories based on archival documents, collaborated with Hugo Racine on a study of the Krupp workforce and their families, which defended the company policies of the Ruhr's heavy-industry sector. This period also saw the founding of the first systematically organized company archives. In Great Britain, George Unwin (1904) published his pioneering work on the origins of the modern enterprise in 1904, which traced the decline of the guilds through to the emergence of functionally differentiated management structures in the seventeenth century.

In the twentieth century, scholarly approaches to business history received a further impulse from technology and from management colleges. Here historical methods were combined with the self-promotional interests of new academic disciplines. College-trained engineers and managers not only wanted to secure their academic standing, but also harbored naive hopes of being able to derive general laws of historical development.

In the nineteenth-century United States, numerous nonacademic business histories on banks, canal companies, and railroads were published. Business history first established itself academically in the 1920s at the Graduate School of Business Administration of Harvard University, which sought to use business history for teaching purposes. Future managers were to be trained through an analysis of historical case studies and through a comparison of past and current methods of executive leadership. With the appointment of Norman Gras to the first-ever chair for business history in 1927, Harvard laid the groundwork for the institutionalization of American business history. In his magnum opus *Business and Capitalism* (1939), inspired by the work of Sombart, Ehrenberg, and Unwin, Gras divided the economic history of America into stages defined by each period's distinctive business type: petty, mercantile, industrial, financial, and national capitalism. The *Casebook in American Business History*, which Gras coauthored with his Harvard colleague Henrietta M. Larson, also appeared in 1939. In 1948, Larson published an extensive bibliography in her *Guide to Business History*. The year before, Gras and Larson had gone a step further down the road to firmly establishing their discipline with the creation of the Business History Foundation. In 1954, the Business History Conference was founded, which has remained the discipline's central American organization to the present day. In this period, periodicals appeared such as the *Journal of Economic and Business History* (1928–32), *Bulletin of the Business Historical Society* (1938–53), and *Business History Review* (since 1954).

Business history received an additional stimulus from the favorable reception of the work of Joseph Schumpeter and his stress on entrepreneurial innovation as the driving force of economic development. Following his programmatic address to the Economic History Association, Schumpeter himself helped to establish the Research Center in Entrepreneurial History (1948–58), funded by the Rockefeller Foundation and the Carnegie Corporation. The scholars associated with the center – Arthur H. Cole, its first director, as well as Thomas C. Cochran, Leland H. Jenks, and the German economist Fritz Redlich – centered their work on the concept of entrepreneurship and sought to anchor it in a broader social context. The Center also

published its own journal, *Explorations in Entrepreneurial History*. In 1959, after 10 years, Cole summarized the Center's most significant findings, which went far beyond those of mere biographical studies. The main emphasis was on the development of entrepreneurial typologies and on the relation of the entrepreneur to the corporation and its environment.

Beginning in the 1940s, more and more American universities, colleges, and business schools introduced courses and chairs in business history. In Germany, business history is primarily taught under the rubric of economic and social history in departments of history or economics. In most other European countries, it is mainly taught at business schools.

The growing interest in business history during the 1950s was reflected in the founding of numerous new scholarly journals, including *Business History* (founded in 1956, United Kingdom), *Tradition* (1956, West Germany; since 1978, *Zeitschrift für Unternehmensgeschichte*), *Technology and Culture* (1958, United States), and *Histoire des Entreprises* (1958, France). Ironically, business history remained a force even when its object of study was undergoing severe periods of crisis. In the wake of the student movements of the 1960s, entrepreneurs and corporations were subjected to harsh criticism. Then, in the 1970s, the pioneer countries of the industrial age lapsed into a structural crisis that, within a few years, had shrunk the long-dominant sectors of mining, iron, steel, and textiles. These upheavals led to the founding of numerous museums and business archives that have since become lively research sites. Added to this were newly established academic organizations such as Germany's *Gesellschaft für Unternehmensgeschichte* (Society for Business History, established 1976).

The maturing of business history as a discipline has been reflected in the emergence of subdisciplines. The 1990s saw the founding of specialized business history journals such as *Accounting: Business and Financial History* (1991), *Financial History Review* (1994), and *Journal of Industrial History* (1998). By contrast, the successor of *Business and Economic History Review* (1962–99), *Enterprise and Society* (2000), began to pose questions inspired and informed by the broader fields of social and cultural history.

The regional embeddedness of much business activity has not infrequently led to the founding of business history museums and archives. Prominent examples are the Center for Business History in Glasgow, Scotland; the Hagley Museum and its affiliated Center for the History of Business, Technology, and Society in Wilmington, Delaware, United States; and the Society for Westphalian Economic History in Germany's Ruhr district. In the 1990s, a number of international organizations were founded, such as the European Association for Banking History (1990) and the European Business History Association (1994). It is a sign of the consolidation and maturation of the field that, in recent years, a growing number of handbooks (Jones and Zeitlin, 2008), textbooks with source collections (Blaszczyk and Scranton, 2006), introductions for students (Berghoff, 2004), and accounts of long-term developments (Landes et al., 2010; McCraw, 2000) have been published.

Methods and Approaches of Business History

From the moment it entered academia, business history began to borrow methodologies from neighboring disciplines, particularly economics and management studies but also from history, sociology, political science, and anthropology. Equally variegated are the research areas and methodologies of modern business history. Roughly speaking, one can distinguish 10 areas of study, which are discussed in the remainder of this section.

Finance Capital and Industrial Production

Stimulated chiefly by Rudolf Hilferding's thesis of the dominance of big banks over industry, the relationship between the financial and the industrial sectors is a focus of analysis. For European and American industrialization, it has been argued that banks and money markets at first played only a subordinate role in the financing of business. However, when these firms reached certain growth thresholds – for example, merging with or investing in capital-intensive technologies – external funding was required, which would lead them into a close relationship with the banking sector.

Of Great Britain, it is said that between 1880 and 1930, London financial institutions neglected industrial interests, thus hindering the modernization and concentration of the country's industrial base. This was in contrast to the big banks of Paris and Berlin. On the other hand, Collins sees the aloofness of the money market to industry as a consequence rather than a cause of slow corporate growth. Davis argues that the American money market *c.*1900 was less efficiently organized than its British counterpart, and the limited availability of credit explains the concentration of capital in the hands of multimillionaires like Rockefeller and Carnegie (Grossman, 2010). By contrast, Chandler emphasizes the dominance of internally generated cash flow as the result of successful integration. Case studies on the close relationship between big banks and industry in Germany show that one cannot speak of a general ascendancy of financial institutions (Fohlin, 2007).

Businesses as Innovators and Users of Technology

Technological innovations, either self-generated or initiated from outside the firm, are central to the development of many enterprises. Thus, business history undertook the description of technical processes; however, this often resulted in uncritical lists of glorious inventions and paeans to the genius of particular entrepreneurs. The new business history discusses questions regarding the timely application of technical innovations or their adequacy for specific conditions of production and sales. In the debates on the competitiveness of different nations, comparative investigations have been particularly enlightening. The mass production technologies that had been suitable for the large and relatively homogeneous American market and a predominantly unskilled labor force were nontransferable – at least with the same level of success – to the completely different economic terrain of Europe. It is also not always an advantage to be in the forefront of technological innovation. Wait and see – then imitate. Later investments in more mature technologies have sometimes proven a superior strategy, especially for countries lagging behind the pioneers of industrial development. Further significant themes in this field are mechanisms of technology transfer, research and development, the relationship of companies and academic research, as

well as the social, economic, and mounting ecological consequences of technical progress.

Organizational Capability, Corporate Governance, and Comparative Advantage

Among the central themes of business history is the quest for an optimal organizational structure with respect to strategy, technology, and the market. Alfred D. Chandler of the Harvard Business School put forward theses on this question that were to preoccupy entire generations of scholars. In his first major work, *Strategy and Structure* (1962), Chandler asserted that changes in the "market – cum – technological environment" modify the "basic long-term goals and objectives of an enterprise,' which themselves determine the shape of the company's organization. Chandler's *The Visible Hand* (1977) stressed the superior performance of managers (i.e., salaried entrepreneurs) in comparison to owner-entrepreneurs. His third notable work, *Scale and Scope* (Chandler, 1990), extended the study to Great Britain and Germany, concluding that differences in national competitiveness were the result of divergent utilization of economies of scale. In employing this approach, Chandler elevated the American model of managerial capitalism and its large-scale "three-pronged investment in production, management, and marketing facilities" to a universal prescription for success.

Chandler's main achievement was that he moved beyond the stage of individual case studies and proposed a general paradigm for the analysis of industrial capitalism. At the same time, his claim to general validity provoked vehement protest. The ensuing debate was very productive but more or less refuted Chandler's idealization of the American model of big industry. His critics complained that Chandler had ignored labor relations, culture, regulation, politics, and smaller companies below the top 200.

Michaele Piore and Charles Sabel (1984) pointed to the viability of historical alternatives to mass production. According to their 'theory of dualism,' mass production is not the only paradigm of industrial capitalism. Small-scale enterprises, always representing the majority of companies, were also able to operate successfully. The most efficient were those specializing in small-market segments and using flexible production technologies along with highly skilled labor. Fluctuations in demand and design could be easily coped with. This 'modern craft production' was a 'necessary complement to mass production' and explains the persistence of the small firm. Multiple paths did coexist, and successful specialty production hinged on quality, differentiation, human skills, and networks rather than on high-throughput technologies and size (Scranton, 1998).

Associated with this debate are questions concerning the optimal size of firms, the reasons for and success of mergers and acquisitions, the relation of transaction costs and corporate structure, and control and governance. Research by Mary O'Sullivan (2000) has shown that, in the 1980s and 1990s, corporate control became more controversial. Previously silent stockholders were empowered by institutional investors and pressed for the maximization of 'shareholder value.' As a consequence, many top executives in the United States and, soon after, Europe subscribed to this maxim, rearranged their incentive structures, and by doing so, fundamentally changed the way their corporations were run. This provoked criticism from other stakeholders, who rightly claimed that their interests also mattered, socially and economically.

Multinationals in the Process of Internationalization and Globalization

Closely connected to the question of appropriate organizational structures is the internationalization process within firms (Jones, 1996). Why do companies prefer foreign direct investments with direct control as opposed to portfolio investments or cooperation with independent foreign partners? Firms like Nobel and Vickers invested abroad in order to exploit competitive advantages acquired at home. By contrast, Shell and Lever secured access to vital raw materials. Others were desirous of skirting customs barriers, operating more closely to the market, or securing foreign know-how, locational advantages, and subsidies. Casson maintains that transaction costs economies caused cross-border market exchange to be substituted by multinational hierarchical organization. Internalization is a superior method of coordination across national frontiers. Related hybrid structures such as joint ventures, cartels, and strategic alliances are also analyzed with the use of similar questions (Casson, 2000).

Firms as a Venue of Social Interaction

The history of work relations was given particular impetus by the classic school of social history. It discovered that in the process of industrialization, many entrepreneurs rose from related occupations like trading or craftsmanship from which they derived important social and financial capital, as well as technological and/or organizational know-how. Their degree of social mobility has long been overestimated. Social history further asks how owners of capital, managers, employees and workers, and men and women organize their social relations within firms. In what ways are individual interests bound together organizationally, and how do they factor into the bargaining process? Thus the focal points of research are the history of unions, of worker participation, and of company social policy, and methods of in-house company relations (Cassis and Minoglou, 2006).

Another area of study is the mechanisms with which top management uses its power and control in the implementation of directives. How is the principal – agent problem solved? That is, in what way is the self-interest of managers and employees curbed with regard to the goals of the entire firm and the capital owners? Chandler sees the rise of better educated managers bereft of family interests as one of the positive and decisive competitive advantages of the American model. He sees the main reason for the relative decline of British industry in its insistence on 'personal capitalism.' Numerous critics have warned against such generalized statements. There is little doubt, however, that the emergence of large company structures frequently coincided with the rise of managers who had no familial connection to the capital owners.

The Survival of the Family Business

In recent decades, family businesses have been reevaluated and acquitted of Chandler's verdict of being generally inferior to

managerial firms and incapable of reaping economies of scale and scope (Colli, 2003). In fact, they are the dominant type of business in most countries. There are many examples of family-controlled and even family-run giant firms and 'global champions'. Moreover, scholars, noting the persistence of family firms, have noted their diversity and stressed their comparative advantages, such as flexibility and lower transaction costs. Family members are often driven by motives beyond short-term financial gain, and they mobilize qualities like loyalty, intrinsic motivation, emotional reward, and long-term commitment. These findings were indirectly given credence by the corporate scandals of the 1990s and 2000s, which dealt a severe blow to the belief in the potential and integrity of managers.

The debate generally assumes a rigid dichotomy between family and managerial businesses, but there in fact exists a broad array of hybrid forms of governance. The recent literature, stressing variety rather than general developmental paths, leaves the impression that family firms, once they have reached a certain size, complexity, and age, are likely to include outside managerial expertise, and, after a phase of hybrid governance, the family's retreat begins.

The small and medium-sized firms of Germany's *Mittelstand* – many of them family owned as well as global champions in specialized niche markets – are no longer seen as relics but rather as models. However, the classic *Mittelstand* model began to be transformed in the 1970s (Berghoff, 2006). The new *Mittelstand* is less dependent on individual families, has more access to external capital, and displays a more international orientation.

Corporations as Cultural Institutions

Firms are bearers of specific corporate cultures that play a key role in internal and external communication. As concerns the internal structure, it is a question of the 'software of organization,' that is, the organization's shared rules and values. While Chandler suggests that the formal structures – the 'hard facts of organization' – are decisive, proponents of cultural business history assert that internal integration and coordination are essentially dependent on the strength of the given corporate culture. This assures loyalty, team spirit, and communication skills while also lowering transaction costs. It consolidates the results of long-term learning processes, especially firm-specific routines and tacit knowledge.

Corporate culture is frequently influenced by strong individuals, chiefly company founders, but also by external socio-cultural factors. Organizational models like those of the bureaucracy, the military, or large agrarian enterprises were especially effective in the industrialization process (Cole, 1959). Following mergers and takeovers, there is often a clash of cultures and incompatibility between differing value systems. Furthermore, it is precisely strong corporate cultures that are subject to inertia that can impede adaptation to external change. Research has shown that organically evolved corporate cultures determine the inner quality of a company in essential ways. However, social engineering – the arbitrary, short-term modification of corporate cultures – is impossible.

Corporate culture not only is effective as an internal link of identity and cohesion but also serves as an exogenous label and a seal of quality. It determines the firm's image in the minds of customers and the broader public, and defines the self-projection of the enterprise and its advertised products. The image-forming power of corporate culture extends to brands that rationalize the communication process with customers, while also implying an adherence to quality standards. The strong trust of such arrangements is central to all forms of marketing but can also be transformed into its diametrical opposite when that trust is abused.

Marketing History

Markets have to be made by marketers, advertisers, market researchers, and other intermediaries between production and consumption. Markets are not perfect mechanisms of self-coordination, and products don't find their way to customers all by themselves. The historical development of markets over the last 200 years or so has done little to cure market imperfections and lessen the need for intermediation. On the contrary, as industrialization and globalization broke down regional and national barriers, markets became much more complex. Rapid technological and cultural change made them ever-faster moving targets for those who sought to understand them. Marketing tries to process information on markets and translate it into a language that corporations can use to steer their operations. Consumers' varying preferences generate insecurity among marketers, who have to develop methods to overcome information asymmetries. This task calls for professional, even scientific, expertise as well as special instruments and institutions.

A number of studies, inspired by cultural history, have examined diverse aspects of corporations' marketing histories, such as the contributions of sales forces (Friedman, 2004) and advertising (Laird, 1998), the marketing efforts of individual firms, the targeting of certain ethnic groups (Walker, 2007), and market research. Other authors have taken a broader perspective and looked at the emergence and transformation of mass markets (Strasser) or the consumer society in general, or at the interaction of these factors (Berghoff et al., 2012).

Companies and Entrepreneurs as Political Actors

Modern companies operate within regulated frameworks. The state establishes legal forms that superintend ownership laws, property rights, responsibilities, and tax and disclosure duties. In addition to company law, labor law, environmental law, trade law, and consumer protection law are also of prime importance. Therefore, it is in the vested interest of the firm to influence the development of regulatory frameworks and to involve itself in the political process. The range of its dealings extends from simple forms of lobbying to participation in *coups d'états*.

Central topics of research are the effects of organized interests; the activity of companies in political parties, parliaments, administration, and governments; the thin line between sponsoring, donations, and corruption; private – public partnerships; the sale of products to the state; the nationalization or privatization of enterprises; and the correlation between business goals and politics in general.

The view of the political role and ethical responsibility of the private sector has gained in significance through research on

the behavior of businessmen in relation to the National Socialist (Nazi) regime. In reaction to the decades-long taboo placed on studies of the Nazi past, numerous works have emerged rejecting ideologically motivated generalizations and accusations, while at the same time confirming the deep involvement of many businessmen in National Socialism. More recent research has demonstrated that this was also true of businessmen in occupied, neutral, and allied countries (Turner, 2005). What is still debated hotly is the extent to which they still enjoyed some autonomy and followed 'normal' commercial considerations or whether they primarily acted under compulsion by the brutal dictatorship (Buchheim and Scherner, 2009; Hayes, 2009).

The Biographical Approach (Entrepreneurial History)

Entrepreneurial history is concerned with the people behind the strategic decisions. What sociocultural variables determined their worldview and thereby their business personality? Such questions were at first chiefly posed by biographical investigations that frequently sought to portray their subjects in heroic terms. Simultaneously, there was the countertradition of critical and even defamatory entrepreneurial biography.

Since the 1970s, social history has introduced quantifying methods into entrepreneurial biography. The great advantage of collective-biographical studies consists in the ability to distinguish between exceptional facts and general structures. Drawing upon selective and representative samples, they investigate heritage, education and upbringing, religion, marital and social status, financial circumstances, the chances of ennoblement, and political influence. One of the most heatedly discussed questions is whether European businessmen became gentrified by imitating the aristocracy and abandoning their own identity, a debate that has led to an overwhelming rejection of this thesis.

Emerging parallel to the wave of collective-biographical works have been several excellent individual biographies, family histories, and large collections of biographical articles (Daumas and Chatriot, 2010). Increasingly, online biographical compilations that include images and other source material are gaining in importance as reference and teaching tools. With the current wave of historiography addressing everyday life and mentalities, biographical methods are currently on the rise. Vivid and atmospheric narratives, including the experiences of spouses, children, and other relatives, now complement more representative statements on general structures that are analyzed through statistical methods.

Conclusion

On the whole, despite its varying status in different countries, business history has firmly established itself as an academic discipline and continues to evolve and expand. It is a field with many cross-discipline connections and a steady exchange with researchers from history, economics, management studies, sociology, political science, and anthropology. As before, there is still the danger of narrow accounts of individual case studies composed with an antiquarian mindset or commissioned histories in the interest of image building, legitimation, or adulation. Although this kind of business history has long been overshadowed by research that fulfills the highest scholarly criteria, publications that present a wealth of material but have little regard for historical context or try to construct heritage stories in the interest of corporate public relations are still published in large numbers. For serious scholars, however, the commitment to macrohistorical and macroeconomic contexts and the inclusion of theoretical approaches from related disciplines have become standard practice.

Abstract

This article discusses the body of statutes, regulations, and case law governing transactions for economic gain among individuals, corporations, partnerships, and other forms of business entities. The laws governing business can be broken down into several basic categories: contracts; agency; employment law; forms of business entities; commercial laws governing the sale of goods, negotiable instruments, and secured lending transactions; product liability; and intellectual property. Other laws affecting the legal environment in which businesses operate are addressed as well, including antitrust and competition law, environmental law, consumer protection laws, regulations governing banking and the offer and sale of securities, and bankruptcy law.

Business law comprises the body of statutes, regulations, and case law governing transactions for economic gain among individuals, corporations, partnerships, and other forms of business entities. The laws governing business can be broken down into several basic categories: contracts; agency; employment laws; forms of business entities; commercial laws governing the sale of goods, negotiable instruments, and secured lending transactions; product liability; and intellectual property. Other laws affecting the legal environment in which businesses operate include antitrust and competition law, environmental law, consumer protection laws, regulations governing banking and the offer and sale of securities, and bankruptcy law.

Modern firms are awash 'in a sea of law' (Edelman and Suchman, 1997). Public law provides the 'rules of the game' (North, 1990) that govern a firm's relationship with its owners, employees, customers, creditors, and competitors. Business law does not just regulate, however; it also enables and facilitates (Suchman et al., 2001). For example, documented property rights, such as recorded deeds to real property, make it possible for entrepreneurs to borrow money collateralized by liens on their assets, thereby converting 'dead capital' into the financial capital necessary to start new firms and expand existing ones (De Soto, 2000). Contract law provides the mechanism whereby individuals and firms can create 'private law' to govern their relationships enforceable by the power of the state.

Law promotes economic growth by protecting property rights, enforcing contracts, allocating risks, facilitating capital markets, creating incentives to innovate, promoting liquid and skilled labor markets, providing economic incentives and infrastructure, and promoting free trade in the global markets (Bagley, 2013). It protects workers by regulating terms and conditions of employment, requiring employers to provide certain benefits, and protecting civil rights in the workplace by banning discrimination or the creation of a hostile environment. Law furthers consumer welfare by promoting safe, low-cost and innovative products and services and by preventing deceptive practices. It promotes public welfare by ensuring national security, promoting the fair and effective administration of justice, collecting taxes and spending money, guaranteeing fundamental rights, and protecting the environment (Bagley, 2013). It thus should come as no surprise that the World Economic Forum found a statistically significant [and positive] relationship between a country's gross domestic product per capita and each of the following: (1) the adequacy of legal recourse, (2) demanding product standards, (3) the extent of intellectual property protection, (4) the effectiveness of the antitrust laws, and (5) stringent environmental regulations (Porter, 2002).

Firms increasingly take an active role seeking to shape the legal environment in which they do business (Bagley, 2010). Legally astute top management teams can use the law and legal tools to increase both the total value created and the share of that value captured by the firm (Bagley, 2008). Conversely, failure to integrate legal considerations into firm strategy can put the firm at a competitive disadvantage and imperil its economic viability.

The remainder of this article focuses on the particular legal doctrines that affect the business environment.

Contracts

A contract is a legally enforceable promise. According to Douglass North and Barry Weingast, "one necessary condition for the creation of modern economies dependent on specialization and division of labor (and hence impersonal exchange) is the ability to engage in secure contracting across time and space" (North and Weingast, 1989, p. 831).

Elements

Formation of a valid contract generally requires four basic elements. First, there must be an agreement between the parties formed by an offer and acceptance of that offer. Second, the parties' promises must be supported by something of value, known as consideration. Third, both parties must have the capacity to enter into a contract. Fourth, the contract must have a purpose that is legal.

Intent to be Bound

As business transactions have grown more complex, courts have wrestled with the issue of when preliminary negotiations have ripened into a contract (Farnsworth, 1987). The leading US case arose out of Pennzoil Company's failed attempt to merge with Getty Oil Company (*Texaco, Inc. v. Pennzoil Co.*, 1987). The court held that a five-page memorandum of agreement, signed by the majority shareholders of Getty Oil and approved (but never signed) by the board, constituted a binding contract under New York law even though a definitive agreement for the $5 billion transaction was never signed.

In Japan, businesspersons are more likely to rely on oral contracts or on short contracts with a broad catch-all provision

stating that the parties will consult in good faith to resolve any questions of interpretation or matters not covered by the contract (Yanagida et al., 1994). As a result, Japanese courts are more likely than their US counterparts to conclude that negotiations have ripened into a binding contract. In addition, as the Japanese High Court explained in a case decided in 1987:

> In the event that preparation between two parties progresses toward conclusion of an agreement and the first party comes to expect that the agreement will surely be concluded, the second party becomes obligated under the principles of good faith and trust to try to conclude the agreement, in order not to injure the expectation of the first party. Therefore, if the second party, in violation of its obligation, concludes that the agreement is undesirable [absent certain circumstances], it is liable for damages incurred by the first party as the result of its illegal acts (Yanagida et al., 1994; pp. 228–229).

The US law imposes more limited precontractual liability under the doctrine of promissory estoppel for the out-of-pocket reliance damage suffered when one party reasonably and foreseeably relies on a promise made during negotiations.

Consideration

In most jurisdictions, each side must provide something of value to form a valid contract. The thing of value, known as consideration, can be money, property, a promise, or a service. Consideration is present if a party agrees to do something that he or she is not otherwise legally required to do or if the party agrees to refrain from doing something that he or she was otherwise legally entitled to do. Courts usually will not scrutinize the value of the consideration, thus giving rise to the adage that even a peppercorn can be adequate consideration. Indeed, under Japanese law, there is no requirement for consideration at all.

Unconscionability

A court will refuse to enforce a contract if it is so oppressive or fundamentally unfair as to shock the conscience of the court. This doctrine of unconscionability dates back to Aristotelian theory and Roman law (Gordley, 1981). The doctrine of *laesio enormis* provided a remedy when the contract price for the sale of goods deviated by at least half from the just price, defined as the market price for similar goods under similar circumstances. German and French laws that relieve a party from its obligations under a contract have their roots in this doctrine. Similarly, in England and the United States, the general principle of freedom of contract has always been limited by the doctrine of unconscionability.

Genuineness of Assent

Even if a contract meets all the requirements of validity (agreement, consideration, capacity, and legality), a court will not enforce it if there has been no true 'meeting of the minds' between the parties. Courts have found no meeting of the minds when there is fraud, duress, or a mistake of fact.

Fraud and duress

There is no meeting of the minds if a contract is tainted with fraud or if one party was forced to enter into it under duress. Thus, a contract is voidable – that is, subject to being undone by one or more parties – if one party induced another to enter into the contract by making false statements, by failing to disclose information when under a legal duty to do so (e.g., when the parties are partners), or by engaging in blackmail or extortion.

Mutual Mistake of Fact

A contract is also voidable if it was predicated on a substantial mutual mistake of fact. For example, in the classic case *Raffles v. Wichelhaus* (1864), two parties had signed a contract in which Wichelhaus agreed to buy 125 bales of cotton to be brought by Raffles from India on a ship named *Peerless*. Unbeknownst to both parties, there were two ships named *Peerless* both sailing out of Bombay during the same year. Raffles meant the *Peerless* sailing in December, and Wichelhaus meant the *Peerless* sailing in October. When the cotton arrived in the later ship, Wichelhaus refused to complete the purchase, and Raffles sued for breach of contract. The court concluded that the mutual mistake of fact had resulted in there being no meeting of the minds and, therefore, no contract.

Mistake of Judgment and Commercial Impracticability

Although a mutual mistake of fact makes a contract voidable, a mere mistake of judgment does not. Therefore, even if a party is mistaken about some aspect of what is bargained for, the contract is still enforceable. For example, the Wisconsin Supreme Court held that a contract to sell a stone for $1 was enforceable when neither party knew at the time that the stone was in fact a diamond (*Wood v. Boynton*, 1885).

Some jurisdictions will relieve a party of its contractual obligations if performance has become commercially impracticable, that is, if performance is made financially impracticable by the occurrence of an event unforeseen by the contract (Eagan, 1980). The added cost of performance must be very substantial before a court will relieve a seller or shipper of its contractual obligations. For example, the House of Lords in the United Kingdom refused to relieve a shipping company of its promise to deliver goods for the agreed-upon price after the closure of the Suez Canal caused the freight costs to double (*Tsakiroglou & Co. Ltd. v. Noblee Thorl G.m.b.H.*, 1960).

Statutes of Fraud

United States

Although most oral contracts are enforceable, almost every state in the United States has statutes requiring that certain types of contracts be evidenced by some form of writing. These Statutes of Fraud require that any (1) contract for the transfer of any interest in real property (such as a deed, lease, or option to buy), (2) promise to pay the debt of another, (3) agreement that by its terms cannot be performed within a year, (4) prenuptial agreement (i.e., an agreement entered into before marriage that sets forth the manner in which the parties' assets will be distributed and the support to which each party will be entitled in the event of divorce), and (5) contract for the sale of goods priced at $500 or more must be evidenced by some writing signed by the party against whom enforcement is being sought.

England, France, and Other Jurisdictions

Although the original Statute of Frauds was adopted in England in 1677, England has repealed all of it except the provisions

relating to transfers of interests in land and promises to pay the debt of others. Many other countries that once had a Statute of Frauds have repealed all or parts of it. France, Japan, and other civil law countries never had a writing requirement.

Remedies

In the event that a valid contract is breached, the other party is entitled to monetary damages or to a court order requiring performance. The nonbreaching party is generally entitled to expectation damages, that is, such amount of money as is necessary to put the plaintiff in the cash position it would have been if the contract had been fulfilled.

Consequential damages, that is, compensation for losses that occur as a foreseeable result of the breach, are also often available. However, if the party suing for consequential damages has suffered lost profits that were not reasonably foreseeable or a natural consequence of the breach, then there will be no award of consequential damages (*Hadley v. Baxendale*, 1854).

Agency

Agency law specifies under what circumstances the contracts entered into by one party (the agent) will bind another (the principal) on whose behalf the agent is acting. Agency law also addresses the question of when the principal will be liable for the torts or civil wrongs of the agent or for crimes committed by the agent. The employer–employee relationship (historically described as the master–servant relationship) is perhaps the most common type of agency in business settings.

Authority to Bind the Principal

A contract entered into by an agent on behalf of the principal is binding on the principal only if the agent had authority to enter into the contract or if the contract is later ratified by the principal. Authority to enter into a contract can be either actual or apparent. Actual authority can be given expressly or can be implied from the nature of the responsibilities the principal has given the agent to fulfill. Apparent authority exists when the principal, either directly or indirectly, leads a third party to believe that the agent has power to act on the principal's behalf.

Respondeat Superior

Under the doctrine of *respondeat superior*, the principal is liable for any torts (and certain crimes) committed by the agent while acting within the scope of employment. A minor detour, whereby the agent deviates from the assigned task, is still considered to have been within the scope of employment unless the deviation is so great as to constitute a frolic, that is, an excursion that in no way furthers the business of the principal.

A principal is more likely to be responsible for activities that otherwise might be deemed frolics when the harm done by the agent was made possible by an instrumentality provided by the principal. For example, if the principal provides the agent a truck to drive, the principal is more likely to be responsible for automobile accidents occurring while the agent is driving the truck even if at the time of the accident the agent was not directly furthering the business of the principal.

In Japan, the employer is not liable for the misdeeds of an employee if the employer exercised due care selecting the employee and supervising the employee's work or if the damages would have arisen even if due care had been exercised.

Employment Laws

Most jurisdictions have statutes and case law setting the minimum wage, imposing limits on the employment of children, giving workers the right to form unions and engage in collective bargaining, and specifying whether an employee without a written employment contract is an employee at-will who can be terminated at any time for any or no reason, or an employee who can be fired only for just cause. In addition, in many jurisdictions, the employment relationship is subject to statutes banning discrimination based on race, color, national origin, religion, sex, or age. For example, in 2007, Japan prohibited discrimination based on age in recruiting and hiring. The United States, the European Union, and India also prohibit discrimination based on disability.

Forms of Business Entities

A fourth body of law fundamental to the conduct of business prescribes the types of entities by which business can be conducted. A business may be conducted as a sole proprietorship owned by one person, a general partnership, a limited partnership, a limited liability company, or a corporation.

Corporations

The most prevalent entity used for large businesses is the corporation. A corporation is a fictitious person that has capacity to enter into contracts and to hold property. The equity of a corporation, evidenced by shares of stock, is owned by the shareholders. The shareholders elect the board of directors, which has the responsibility for managing the corporation. The board elects the officers, such as the president, treasurer, and secretary, who report to the board and serve at its pleasure.

Corporate governance

The respective rights and obligations of shareholders, directors, and officers of a corporation are dictated by the statutes of the jurisdiction in which the corporation is formed. For example, in the state of Delaware, where more than half of the Fortune 500 companies are domiciled, the board of directors has broad latitude to determine when it is in the best interests of the corporation to rebuff a hostile takeover offer (Bagley, 2013).

Jurisdictions vary significantly in their treatment of corporate stakeholders, such as employees, customers, suppliers, and communities. In large German corporations, codetermination statutes require that half of the supervisory board be elected by the employees and labor unions and councils. In Japan,

boards traditionally included no nonexecutive directors and put the welfare of the employees before shareholder return. In the United States, shareholder primacy tends to be the rule, at least once a decision has been made to sell control of the corporation or to break it up (Bagley and Page, 1999).

Limited Liability

A key advantage of a corporation is the limited liability it provides to its owners. Absent facts justifying piercing the corporate veil, such as the commingling of personal and corporate assets or the shareholders' disregard for the corporate form, the shareholders are not liable for the debts of the corporation. In contrast, in a general partnership, each of the general partners is personally liable for the debts and other obligations of the partnership. Similarly, the owner of a sole proprietorship is personally liable for all debts of the business. In a limited partnership, the managing partner has the same unlimited liability as a general partner in a general partnership, but the limited partners have no liability beyond their capital contribution unless they actively participate in management. In the case of a limited liability company, the owners (called members) have limited liability even if they are active in the management of the business.

Commercial Laws Governing the Sale of Goods, Negotiable Instruments, and Secured Lending Transactions

Because of the key role played by purchases and sales of goods in virtually every type of business, many jurisdictions have specific statutes designed to facilitate their sale. These statutes modify certain of the general contract rules discussed earlier in this article. Commercial laws also govern the creation and transfer of negotiable instruments and the lending of money secured by property.

Uniform Commercial Code

For example, in the United States, every state other than Louisiana has adopted a version of the Uniform Commercial Code (UCC).

Sale of Goods

The provisions in UCC Article 2 concerning the sale of goods eliminate many of the formalities required under the common law. For example, the UCC abolishes the 'mirror image rule,' which requires that an acceptance be identical in terms to the offer. Instead, the UCC acknowledges that sales transactions are often represented by an exchange of preprinted forms with additional or conflicting terms (the 'battle of the forms'), and it provides guidance as to which terms will be deemed to be part of the contract.

Negotiable instruments

Article 3 of the UCC governs negotiable instruments, including drafts, checks, notes, and certificates of deposit. The most common type of draft is a check: the writer of the check is the drawer; the bank on which the check is drawn is the drawee; and the person to whom the check is payable is the payee. Article 3 sets forth the requirements for negotiability: a writing signed by the maker or drawer containing a definite and unconditional promise or order to pay a fixed amount of money on demand or at a definite time. It also specifies what endorsements are required to negotiate an instrument payable to order, such as a check.

The UCC prescribes the rights given a holder in due course, that is, the holder of a negotiable instrument who took it for value, in good faith, and without notice that it had been dishonored or that any person has a defense against or claim to it. Unlike an ordinary holder who has only those rights that the transferor had, a holder in due course takes the instrument free of most of the defenses and claims to which the transferor was subject.

Secured Lending Transactions

Article 9 of the UCC governs transactions in which payment of a debt is guaranteed, or secured, by property owned by the debtor. It permits the secured party to perfect its security interest by filing a financing statement or, in some cases, by possession of the collateral. In general, the first to perfect has priority over other third parties who may wish to have their debts satisfied out of the same collateral.

Convention on Contracts for the International Sale of Goods

Most sales of goods involving parties in more than one country are governed by the Convention on Contracts for the International Sale of Goods (CISG), unless the parties expressly opt out of CISG. Unlike the UCC, CISG requires that the terms of the acceptance mirror those of the offer. It provides that an offer is irrevocable if the offeror orally states that it is irrevocable, or if the offeree reasonably relies on the offer as being irrevocable. In contrast, the UCC requires that an irrevocable offer not supported by consideration be in writing. Under CISG, the parties must specify the price or provisions for its specification, whereas the UCC requires that only the quantity be specified.

CISG imposes a duty for merchants to conduct themselves in good faith (Duncan, 2000). Thus, for example, a buyer may not arbitrarily deny a seller's request for additional time to deliver goods. This contrasts sharply with the UCC's perfect tender rule, which permits a buyer to reject goods not conforming perfectly to the contract.

Product Liability

Most jurisdictions impose strict liability on the sellers of goods for defective products, that is, liability without regard to fault. For example, the Council of Ministers of the European Union adopted a directive in July 1985, which made manufacturers and producers strictly liable for injuries caused by defects in their products. In certain jurisdictions, there is no strict liability in defective design cases. Instead, the plaintiff has the burden of proving that there was a defect in the product that could reasonably have been avoided by the use of an alternative design.

Intellectual Property

Intellectual property is any product or result of a mental process that is given legal protection against unauthorized use. It includes patents, copyrights, trademarks, and trade secrets.

Patents

A patent is a government-granted right to exclude others from making, using, or selling an invention for 20 years after the date the patent application is filed. A utility patent, the most common type of patent, protects any novel, useful, and nonobvious process, machine, manufacture, or composition of matter. In certain jurisdictions, human-made living organisms can be patented, as can computer software and business processes.

Copyrights

Unlike a patent, which can protect an idea, a copyright protects original expressions fixed in a tangible medium, such as books, records, musical scores, and films. Although registration of a copyright gives the author certain additional rights, the copyright is created as soon as the work is fixed in a tangible medium of expression. Under the Berne Convention, most industrialized countries give persons with a copyright under the laws of another jurisdiction the same rights that a national would have under local law.

Trademarks

A trademark is a word, name, symbol, or device used by a manufacturer to identify and distinguish its goods from those manufactured by others and to indicate the source of the goods. Examples include Coca-Cola, Marlboro, and Nescafe. A service mark, such as Barclays, is similar but is used in connection with services.

Trademarks are granted for a particular field of use, for example, nonalcoholic beverages or automobiles. Thus, more than one company can register the same mark. The importance of a company's domain name, or electronic address, for Internet branding purposes, and the fact that domain names contain no field-of-use restriction, have required courts to consider when use of a trademark within a domain name constitutes trademark infringement. Courts have ruled against 'cybersquatters,' who register a trademarked name as a domain name to force the trademark owner to buy the domain name. They also have found infringement when the company using the domain name offers the same or similar products as the trademark owner or uses the name in a way that dilutes or tarnishes a famous mark. For example, Hasbro, owner of the trademark Candyland for a children's game, was able to force the owner of Candyland.com to stop using the domain name for a pornography site.

Trade Secrets

A trade secret is information, including a customer list, formula, compilation, or process, that derives independent economic value from not being generally known and is the subject of reasonable efforts to maintain its secrecy. Perhaps the most famous trade secret is the formula for Coca-Cola. In response to perceived problems facing US businesses from foreign theft of trade secrets, the United States adopted the Economic Espionage Act in 1996, which imposes criminal liability (including fines and prison sentences) on any person who knowingly steals a trade secret or knowingly receives a wrongfully obtained trade secret.

In 1997, Volkswagen AG (VW) paid General Motors (GM) Corporation $100 million to settle allegations that VW's purchasing chief stole trade secrets, including plans for future GM models and car-building techniques, when he left GM to join VW. Under the emerging doctrine of inevitable disclosure, an employer can challenge a former employee's decision to work for a competitor if the new position would result in the inevitable disclosure or use of the former employee's trade secrets.

Other Laws Affecting the Legal Environment of Business

Other laws affecting the legal environment in which businesses operate include antitrust and competition law, environmental laws, consumer protection laws, regulations governing the offer and sale of securities, and bankruptcy law.

Antitrust and Competition Law

Cases brought by the European Commission and the US Justice Department against Microsoft Corporation and Google Inc. have required regulators and courts to wrestle with the question of how to reconcile the exclusionary rights arising out of intellectual property law with the bans on anticompetitive behavior and abuse of dominant position contained in such laws as the Sherman Act in the United States, Articles 85(1) and 85(2) of the Treaty of Rome in the European Union, and the Act of Prohibition of Private Monopolization and Maintenance of Fair Trade in Japan. Regulators in the European Union, the United States, and China can block mergers that would unduly limit competition even if neither merger partner is domiciled in that jurisdiction.

Environmental Laws

In response to high-cost hazardous waste spills and clean-ups, a number of jurisdictions have adopted laws governing the storage, transport, and disposal of hazardous waste. The European Union and Taiwan have adopted the policy that the polluter pays, with the objectives of protecting the quality of the environment and human health and promoting the prudent and rational utilization of natural resources. The United States imposes liability not only on the person who stored, transported, or disposed of the waste, but also on the owner or operator of the property at the time the waste is discovered. Increasing concerns about climate change have led to stricter limits on the release of greenhouse gases, such as carbon dioxide.

Consumer Protection

Jurisdictions continue to adopt laws and regulations to protect consumers from deceptive sales practices and advertising. The rise of the Internet and social networks, as well as the ease

with which electronic databases can be used to collect personal data, have sparked new concerns about consumer privacy and more stringent government oversight.

Financial Regulation

The United States has the most restrictive rules regarding the offer and sale of securities, such as common and preferred stock and bonds. Generally, any public offering of securities must be made pursuant to a registration statement declared effective by the Securities and Exchange Commission (SEC). The most important part of the registration statement is the prospectus, which contains detailed information about the company issuing the securities and its management, principal shareholders, business, and financial condition. The Jump-start our Business Startups Act of 2012 (the JOBS Act) created new exemptions for public offerings using the Internet and reduced the disclosure requirements for "emerging growth companies," defined as firms with less than $1 billion in annual revenues. Manchester United relied on these new provisions when it went public on the New York Stock Exchange in 2012. The US laws provide civil and criminal penalties for any offer or sale of a security, regardless of whether it is registered, involving a misstatement of a material fact or an omission that makes the facts stated materially misleading. SEC Regulation S facilitates the offering of securities outside of the United States by US firms by exempting many such offerings from the burdensome US registration requirements that would be applicable if the securities were sold within the United States.

The subprime mortgage crisis of 2008, which contributed to a global financial crisis, led to more stringent regulation of banks and the other financial institutions. They include heightened net capital requirements and greater regulation of financial derivatives, such as credit-default swaps.

Bankruptcy Law

The principle that a debtor should be permitted to discharge certain debts has ancient roots. As early as 1400 BC, Mosaic Law required unconditional forgiveness of debts every seven years. The British Parliament under King Henry VIII passed a Bankruptcy Act in AD 1542 to regulate failing English merchants.

A key objective of bankruptcy law is to ensure that creditors and equity holders of financially distressed businesses are treated fairly in a judicial setting designed to ensure the efficient handling of claims. In general, creditors must be paid in full before equity holders receive anything.

The United States provides perhaps the most prodebtor bankruptcy relief available. An insolvent firm in the United States generally can elect to liquidate its assets or to reorganize the business, often with the debtor still in control. In contrast, in Australia, creditors can force the liquidation of a company that cannot pay its debts even if the debtor argues that the business would be worth more as an operating whole. Some countries, such as Germany, do not provide for the complete discharge of debts in bankruptcy, only arrangements for their payment over time.

Business Models

Raphael Amit, University of Pennsylvania, Philadelphia, PA, USA
Christoph Zott, IESE Business School, Barcelona, Spain

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A firm's business model is a template that depicts the way the firm conducts its business. It describes the system of interdependent activities that are performed by the firm and by its partners and the ways that these activities are linked to each other through transactions in factor and product markets. In this article, we focus on the evolution of business model research during the last 10 years and explain the various ways in which the business model has been conceptualized. We review scholarly work on business models within the fields of strategic management, entrepreneurship, and innovation.

Introduction

A business model is crafted by a focal firm's managers in order to best meet the perceived needs of their customers. The business model is a template that depicts the way the firm conducts its business. It describes the system of interdependent activities that are performed by the firm and by its partners and the mechanisms that link these activities to each other.

An activity in a focal firm's business model can be viewed as the engagement of human, physical, and/or capital resources of any party to the business model (the focal firm, end customers, vendors, etc.) to serve a specific purpose toward the fulfillment of the overall objective. An activity system is a set of interdependent and interconnected activities that are centered on a focal firm; it encompasses activities that are conducted either by the focal firm or by partners, customers, or vendors. To fully address the market opportunity, the firm's activity system may transcend the focal firm and span across the firm and its industry boundaries, but it remains firm-centric, enabling the focal firm not only to enhance total value with its partners, but also to appropriate a share of the value created.

A focal firm's business model thus has two objectives: (1) to create value for all business model stakeholders (commonly referred to as the 'value proposition'); that is, to fulfill customers' needs and create customer surplus while generating a profit for the focal firm and all its partners (Amit and Zott, 2001), and (2) to appropriate value for the focal firm.

Later in the article, we briefly describe various approaches toward conceptualizing business models. We then review some key contributions to business model research in the areas of strategic management, entrepreneurship, and innovation. We conclude with a future research agenda.

Business Model Conceptualizations: A Brief Overview

At this stage in the evolution of the business model concept, a unified view has not yet emerged, as different conceptualizations of the business model emphasize different aspects of wealth creation (Zott et al., 2011). Broadly speaking, some concepts center on value creation, while others focus more on value appropriation through, for example, revenue generation. The value creation perspective of the business model has been advanced in a series of articles by Amit and Zott (2001), Zott and Amit (2007, 2008) to capture the essence of 'how firms do business.' These studies have begun to describe the business model as a source of innovation, for example, when it connects previously unconnected parties, links transaction participants in new ways, or introduces new transaction mechanisms. McGrath (2010) concurs with this value creation view of the business model. According to her definition, business models include two core managerial choices: units of business (i.e., what a firm is selling that someone is prepared to pay for) and the set of activities employed to sell those units.

Other authors have proposed a more encompassing definition of the term, with greater emphasis on value appropriation (e.g., Casadesus-Masanell and Ricart, 2010). Chesbrough and Rosenbloom (2002: 529), for example, link the business model to the technology management literature and define it as the "heuristic logic that connects technical potential with the realization of economic value," emphasizing its role in linking technology to market outcomes. Consistent with this perspective, Casadesus-Masanell and Ricart (2010) posit that one important component of business models is the set of choices made by management regarding how the organization operates, such as compensation practices, procurement contracts, location of facilities, or assets employed. Another component of business models, according to this view, is reflected in the consequences of these choices, such as low cost or a culture of frugality.

Despite the absence of a clear consensus in the literature about the concept definition, researchers have begun to converge on some common themes characterizing business models (Zott et al., 2011): (1) business models center on the logic of how value is created for all stakeholders, not just how it is captured by the focal firm; (2) activities performed by the focal firm as well as by partners, suppliers, and even customers play an important role in the various conceptualizations of business models that have been proposed; (3) business models emphasize a system-level, holistic approach toward explaining how firms 'do business'; and (4) the business model is emerging as a new level and unit of analysis. Together, these emerging themes point toward the business model as a concept that extends that of the value chain (Porter, 1985) by (1) emphasizing value creation and delivery dynamics, (2) spanning firm and industry boundaries, and (3) allowing for a nonlinear sequencing of interdependent activities. Although the notion of the business model draws on arguments that are central to the value chain framework, in

particular on the ideas that activities and multiple sources of value matter, it extends those arguments in important ways.

The business model concept became prevalent with the development of the Internet in the mid-1990s. Since that time, the concept has resonated first with practitioners and then with academics in such fields as strategic management, entrepreneurship, and innovation.

Business Models and Strategic Management

Scholars have emphasized that the business model can play an important role for a firm's strategy. Firm strategy could indeed be viewed as having two broad components: the firm's competitive positioning and its underlying business model, with the latter complementing the former. In support of this argument, Zott and Amit (2008) examine the possible contingent effect of business model design in mediating between product market strategy and firm performance. They ask: How do the firm's business model and product market strategy interact to impact the firm performance? They find that business models that emphasize novelty and are coupled with either differentiation or cost leadership product market strategies can have a positive impact on the firm's performance; and novelty-centered business models together with early entry into a market have a positive effect on performance. Thus, business model design and product market strategy are complements, not substitutes (Zott and Amit, 2008).

According to Teece (2007, 2010), the business model reflects a "hypothesis about what customers want, and how an enterprise can best meet those needs, and get paid for doing so" (2007: 1329); it "embodies nothing less than the organizational and financial 'architecture' of the business" (2010: 173). However, is the business model part of a firm's strategic repertoire (i.e., a strategic tool in and of itself) or is it an expression of the firm's strategy? According to Richardson (2008), the business model explains how the activities of the firm work together to execute its strategy, thus bridging strategy formulation and implementation. In a similar vein, Casadesus-Masanell and Ricart (2010) view the business model as a reflection of a firm's realized strategy.

An important factor of interest to strategy scholars is the focus of the business model concept on the value proposition to its stakeholders and a generalized emphasis on the role of the customer, which appears to be less pronounced elsewhere in the strategy literature. A common view seems to have emerged that the business model revolves around customer-focused value creation (Chesbrough and Rosenbloom, 2002; Teece, 2007, 2010; Zott et al., 2011). Viewed from this perspective, the business model embodies the essential details of a firm's value proposition for its various stakeholders, as well as the activity system the firm uses to create and deliver value to its customers (Zott and Amit, 2010).

Increasingly scholars also acknowledge that firms do not execute their business models in a competitive vacuum, and that they can indeed compete through their business models (Casadesus-Masanell and Ricart, 2010). The business model, then, represents a potential source of competitive advantage, one that is distinct from the firm's product market position (Zott and Amit, 2008).

Business models can thus play a central role in explaining firm performance. They complement a firm's product market strategy (Zott and Amit, 2007), embody its value proposition to customers and other stakeholders, and describe how that value is created and delivered through the firm's (possibly boundary spanning) activity system. Correspondingly, Afuah and Tucci (2001: 3) propose the business model as a unifying construct for explaining competitive advantage and firm performance and define it as "the method by which a firm builds and uses its resources to offer its customer better value and to make money in doing so."

Business Models and Entrepreneurship

In addition to importance in the field of strategic management, business models are also relevant for entrepreneurship. The entrepreneur could be portrayed as the architect of the activity system of a new venture, as a creative designer (and, potentially, innovator) of economic exchanges, a description which complements received notions of entrepreneurs as product and process innovators. The business model concept is thus central to entrepreneurship.

Consistent with the theoretical development by Amit and Zott (2001), entrepreneurs' business models can create value through efficiency (emphasized by transaction costs economics), novelty (Schumpeterian innovation), complementarities (advocated by resource-based theory), and lock-in (inherent in strategic networks). The emphasis of the business model perspective on value creation calls for integrating important entrepreneurship and strategy theories and potentially heightens our understanding of the complex processes and mechanics that drive wealth creation.

Zott and Amit (2007, 2008) show empirically that the design of the business model is indeed central to wealth creation through entrepreneurship. In particular, Zott and Amit (2007) have analyzed the performance implications for entrepreneurial firms of business model designs by considering two distinct effects: the total value creation potential of the business model and the focal firm's ability to appropriate that value. They hypothesize that the greater the total value created, and the greater the entrepreneurial firm's bargaining power, the greater the amount of value that the focal firm can appropriate. How much of the possible total value is actually captured, however, depends on the revenue model chosen by the entrepreneur. The researchers find through large sample, cross-sectional empirical analyses of start-ups that introducing novel business models positively influences entrepreneurial firm performance, even when the environment switches from resource-rich to resource-poor.

In line with these findings, Hargadon and Douglas (2001) point to the crucial role of the design of the business system for entrepreneurial innovation. Such design is centered on "a particular set of understandings and interactions" (2001: 494) between different stakeholders, such as the firm and its customers. As Romme (2003) notes, the purpose of design is to produce systems that do not yet exist – a key task for entrepreneurs. Indeed, in (re-)designing their business models, entrepreneurs throughout the world, in new as well as existing companies, have been leveraging recent technological

developments. Among other things, this has contributed to a shift in the locus of competitive advantage from the venture and its internal stakeholders (e.g., management, shareholders, and employees) to its activity system, which encompasses external stakeholders such as partners, vendors, and customers. Thus, both new and established firms have become increasingly interested in innovating their business models.

Business Models and Innovation

Rapid advances in information and communication technologies have facilitated new types of technology-mediated interactions between economic agents and enabled firms to fundamentally change the ways they do business (Bock et al., 2012; Chesbrough, 2010; Dewald and Bowen, 2010; Sako, 2012). Because of that, senior managers of focal firms have more possibilities in how they pursue innovation. For example, besides innovating products, processes, and management practices, they can now also innovatively design new business models along various dimensions, for example, construct, link, and/or sequence boundary-spanning exchanges and activities (Amit and Zott, 2012). For instance, Chesbrough (2010) argues that business model innovation provides a tool for value creation, complementing new technologies. He proposes ways to overcome business model innovation barriers through experimentation and successful leadership of organizational change. Bock et al. (2012) analyze the perceptions of 107 CEOs and find that business model innovation effort in companies positively moderates the relationship between activity reconfiguration and strategic flexibility. Dewald and Bowen (2010) analyze the reactions of incumbents to the introduction of new business models and find that incumbent managers are less likely to adopt the new business model when innovation is perceived as a threat than when it is perceived as an opportunity. Sanchez and Ricart (2010) explore business model innovation in low-income markets and distinguish between isolated and interactive new business models introduced by firms in those markets.

Business model innovation seems to be of growing importance. A study from the Economist Intelligence Unit (2005: 9) found that a majority of the more than 4000 senior managers who were surveyed worldwide favored new business models over new products and services as a source of future competitive advantage. The study stated that, "the overall message is clear: how companies do business will often be as, or more, important than what they do." In a similar study conducted by IBM (Pohle and Chapman, 2006) in which over 750 corporate and public sector leaders from around the world were interviewed on the subject of innovation, "one key finding was that competitive pressures have pushed business model innovation much higher than expected on CEOs' priority lists" (2006: 35). Indeed, the study found that outperforming companies whose operating margins had grown faster than their competitors' over the previous 5 years were twice as likely as their lower performing peers to emphasize business model innovation, as opposed to product or process innovation.

Much of the prior research on business model innovation has considered the extent to which business models are *de novo*, that is, new to the state-of-the-art, and not just new to the firm (Birkinshaw et al., 2008). Nidumolu et al. (2009) view the development of new business models as a key step in their five-stage model of corporate transformation to become environmentally sustainable. They declare as the central challenge "to find novel ways of delivering and capturing value, which will change the basis of competition" (2009: 60). According to the authors, opportunities for business model innovation lie in developing new delivery technologies that change the value chain, in combining digital and physical infrastructures, or in turning products into services. Similarly, Johnson et al. (2008) focus on *de novo* business models, based on the belief that there is "no point in instituting a new business model unless it is not only new to the company, but in some way game-changing to the industry or market" (2008: 58). Changes to business model design, however, can also be subtle and new to the firm; they may not have the potential to disrupt an industry, but could still yield important benefits to the business model innovator (i.e., the focal firm).

The novelty presented by new business models can result in superior value creation and replace the old way of doing things to become the standard for the next generation of entrepreneurs to beat. Some scholars have suggested very broad domains for business model innovation, in line with their corresponding definitions of the business model concept. Mitchell and Coles (2003), for example, propose that business model innovation involves modifications in the 'who,' 'what,' 'when,' 'why,' 'where,' 'how,' or 'how much' involved in providing products and services to customers. Similarly, Johnson et al. (2008) describe business model innovation as involving the firm's value proposition, target customers, product and service offering, resources (such as people, technology, or equipment), revenue model, cost structure, processes, rules, and norms.

The business model can thus represent a new subject of innovation, which complements the traditional subjects of process, product, and organizational innovation, and involves new forms of cooperation and collaboration. It can, however, also simply help firms commercialize innovative ideas and technologies by unlocking the value potential embedded in new technologies and converting it into market outcomes. Chesbrough and Rosenbloom (2002) detail an extensive case study, in which they show how the Xerox Corporation grew in part by employing an effective business model to commercialize a technology rejected by other leading companies. The study also compares successful and unsuccessful technology spin-offs with comparable market potential and finds that in successful ventures the search and learning for an effective business model was significantly higher than in failed ventures. Björkdahl (2009) argues that the integration of new technologies into the technology base of a product (i.e., technology cross fertilization) can open up new subspaces in the existing technical performance and functionality space, which in turn requires a new business model if the economic value potential of the new technology is to be captured.

Business models can not only entail consequences for technological innovations, they are also shaped by them. Technological innovation can trigger changes in the company's operational and commercial activities, and hence in the business model.

Opportunities for Future Research

Research on business models needs to be advanced through both theory development and empirical analysis. Increasing consensus on the theoretical foundations, the definition, and the fundamental properties of business models should lead to the emergence of broadly accepted concepts and typologies, which are currently lacking. Such research will help deepen our understanding of the linkages between value creation and value appropriation. Empirical research on the measurement of business model innovation, structured to capture all lines of a firm's business that have revenue potential, holds great promise to enhance our understanding of business models. Examining the dynamics of business model evolution, how they emerge, and how they are shaped and adapted by entrepreneurial actors over time – as well as how business models coevolve with product market strategy and organization design – reflects an important cross-disciplinary research program that will substantially solidify the business model as a pivotal unit of analysis in our understanding of value creation and capture.

Conclusion

We are still in the early stages of developing the business model as a new unit and level of analysis for strategy, entrepreneurship, and innovation research. Theoretical, empirical, and field research on the foundations and evolutions of business models promises to broaden our understanding of this important concept.

Business Platforms

Abstract

This article reviews the literature on platforms and sheds light on the design principles, economics fundamentals, and business strategies associated with platforms. We divide the discussion into two main types: product platforms designed by individual companies or assemblers of closed supply chains to develop new products or services on the basis of common and reusable components and architectures, and industry platforms which act as a foundation for an ecosystem of firms to develop a set of interrelated products and services. Present in a variety of organizational contexts, platforms create value for innovative ecosystem participants by structuring the innovation process around core and complementary elements and by creating the network effects that accelerate the adoption and use of platforms. With increased globalization of innovation capabilities, we expect the phenomenon of platforms to become an important new form of industrial organization. We conclude with highlighting concerns associated with platform dominance.

Business platforms, both internal to the firm and at the industry level, have become increasingly important in a large number of markets, especially with high-technology products that require complementary innovations from various firms to be truly valuable to end users. There is considerable confusion, however, as to what the term 'platform' refers to in practice and in management-related research. This article reviews different types of platforms commonly discussed in the management literature and attempts to define more precisely the characteristics of a specific types of platforms. We also discuss managerial practices associated with effective platform leadership as well as gaps in our current knowledge and avenues for future research. (This article draws extensively on prior writings by the authors, especially Gawer, 2009b and Gawer and Cusumano, 2013, 2014.)

Main Types of Platforms

What managers and researchers refer to as platforms exist in a variety of industries, especially in high-technology businesses that involve multiple products and services. For example, Microsoft, Apple, Google, Intel, Cisco, ARM, Qualcomm, EMC, and many other firms design or build hardware and software products and components for computers, cell phones, and consumer electronics devices. Many of these products have been referred to in the business press and in scholarly literature as 'platforms' or key platform elements (Gawer and Cusumano, 2002; Eisenmann et al., 2006; Gawer, 2009a). In addition, these firms and their partners as well as customers are also said to participate in platform-based 'ecosystems' (Moore, 1996). While the term platform is used in many ways, most scholars seem to agree that platforms are distinct from conventional products in that they have the potential to generate positive feedback loops, also called 'network effects,' between the primary product (the platform) and its users as well as with complementary products and services. In other words, the more users who adopt the platform, and the more third-parties that create complementary products and services, the more valuable the platform becomes to the owner and to the users. The positive feedback loops create increasing incentives for more users and more complementors to adopt a particular platform and join a particular ecosystem.

Platforms can also operate in relation to other platforms. For example, the Intel x86 line of microprocessors have served as essential elements of the personal computer platform, with Windows 'sitting on top' to control the hardware as well as create a foundation for launching applications and other functions such as accessing the Internet through a browser. Other microprocessor designs and operating systems form key elements of smartphone platforms dominated by Google and Apple to access the Internet and the phone network or run a variety of applications. Search engines such as from Google and Microsoft as well as social media networks such as from Facebook, Skype, and LinkedIn exist on top of the Internet.

A number of researchers have studied platforms from various perspectives. For example, we have research on new product development from the innovation and operations management fields (Meyer and Lehnerd, 1997); research on platform-based competition in the strategy field (Gawer and Cusumano, 2002, 2008; Eisenmann et al., 2006); and analyses of the economic implications of platform competition and dynamics in the economics field (Rochet and Tirole, 2003; Armstrong, 2006). But our review of the literature and numerous industry examples suggests that these and other scholars have largely been describing two predominant forms of platforms: product platforms, used mainly for product development, and industry platforms, used to create value and innovations at the ecosystem level. We can consider both types as 'business platforms' in that the primary actors, apart from individual users, are firms or networks of firms functioning as suppliers and partners.

In short, we define product platforms as a set of assets organized in a common structure from which a firm can efficiently develop and produce a stream of derivative products (Muffatto and Roveda, 2002). We define industry platforms as products, services, or technologies that are similar in some ways

to the former but provide the foundation upon which an entire industry ecosystem, including both the platform owner and third-party firms as well as users can develop their own complementary products, technologies, or services (Gawer and Cusumano, 2002; Gawer, 2009b). The following sections elaborate on these distinctions as well as the importance of network effects to the second type of platform.

Product Platforms

The first popular usage of the term platform seems to have been in the context of new product development and incremental innovation around reusable components or technologies. We refer to these as product platforms in that a firm, either working by itself or with suppliers, can build a family of related products or sets of new features by deploying these components. For example, Wheelwright and Clark (1992) describe how various companies developed 'product platforms' to meet the needs of different customers simply by modifying, adding, or subtracting different features. Other research in this vein tends to define these kinds of platforms as subsystems and interfaces that form a common structure from which a company can efficiently develop and produce a family of products, such as new automobiles or consumer electronics devices. Robertson and Ulrich (1998) propose an even broader definition, viewing platforms as the collection of assets (i.e., components, processes, knowledge, people, and relationships) that a set of products share. In the marketing literature, Sawhney (1998) even suggests that managers should move from 'portfolio thinking' to 'platform thinking,' which he defines as understanding the common strands that tie the firm's offerings, markets, and processes together, and exploit these commonalities to create leveraged growth and variety.

These and other researchers have identified, with a large degree of consensus, several potential benefits of product platforms: savings in fixed costs; efficiency gains in product development through the reuse of common parts and 'modular' designs, in particular, the ability to produce a large number of derivative products with limited resources; and flexibility in product feature design. One key objective of platform-based new product development seems to be the ability to increase product variety and meet diverse customer requirements, business needs, and technical advancements while maintaining economies of scale and scope within manufacturing processes.

The empirical evidence indicates that, in practice, companies have successfully used product platforms to increase product variety, control high production and inventory costs, and reduce time to market. Most of the early research is about durable goods, whose production processes involve manufacturing, such as in the automotive, aircraft, equipment manufacturing, and consumer electronics sectors (Sanderson and Uzumeri, 1997; Cusumano and Nobeoka, 1998). Researchers have also identified a few fundamental design principles or 'design rules' that appear to operate in product platforms, in particular the stability of the system architecture, and the systematic or planned reuse of modular components (Baldwin and Woodard, 2009). We can see as well a fundamental trade-off couched in terms of functionality and performance: the optimization of any particular subsystem may result in the suboptimization of the overall system (Meyer and Lehnerd, 1997). In this sense, product platforms may promote only incremental innovation or constrain some types of innovation – a theme that we will return to later in this article.

We also view supply chains as a special kind of product platform. In a supply chain, a set of firms follow specific guidelines to supply intermediate products or components to the product owner or the final product assembler (Doran, 2004). The objective is also to improve efficiency and reduce cost such as by the systematic reuse of modular components. Major potential benefits are that a firm with access to a platform supply chain can tap into external capabilities to find more innovative or less expensive components and technologies. At the same time, the product or platform owner may have less control over the components and technology, which can have its own negative consequences. Supply chain platforms are commonly discussed with regard to assembly industries such as consumer electronics, computers, and automobiles. We can also link this literature to other research on industry architecture (Jacobides et al., 2006).

The research suggests that there are distinctions between supply chains and industry platforms. One is that, in the latter case, the firms developing the complementary innovations – such as applications for Windows or the Apple App Store – do not necessarily buy from or sell to each other. Nor are they usually part of the same supply chain or share patterns of cross-ownership, such as Toyota does with its major component suppliers. There also are no obvious network effects between the main product or platform and components in a supply chain platform, though when this does occur, we are probably viewing an embedded industry platform. For example, an auto parts supplier might develop a new fuel-injection system and provide it to a particular automaker. Other automakers then decide to adopt this technology and redesign their engines to work with this new fuel-injection system. Independent software companies start providing new programing applications that optimize performance of the fuel-injection system under different driving conditions. Other parts suppliers redesign their components to work with the new fuel-injection system. The fuel-injection system, once simply part of one firm's supply chain, has gradually become an industry-wide platform within the automobile industry, with its value considerably enhanced by the efforts of multiple firms.

Industry Platforms

We have defined industry platforms as products, services, or technologies developed by one or more firms, and which serve as foundations upon which a larger number of firms, organized in an ecosystem, can build further complementary innovations and potentially generate network effects. There is a similarity to product platforms in that industry platforms provide a foundation of reusable common components or technologies, but they differ in that this foundation is 'open' to outside firms. The degree of openness can also vary on a number of dimensions – such as level of access to information on interfaces to link to the

platform or utilize its capabilities, the type of rules governing use of the platform, or cost of access (as in patent or licensing fees).

There are some similarities between the concept of an industry platform and that of a dominant design. A 'dominant design' (Abernathy and Utterback, 1978), when it emerges, sets the standard for what form and features users expect a particular product to take in the future. The two concepts differ, however, in that the purpose of an industry platform is to bring multiple parties within the industry together – primarily users and complementors. Moreover, like product company platforms, industry platforms do not simply emerge without deliberate, firm-driven agency, or deliberate managerial decisions and actions. And in platform markets – those industries characterized by a foundation technology around which third-party firms create complementary innovations, with adoption driven by positive feedback loops and network effects – the most likely winner is not necessarily the originator of the dominant design or the owner of the most elegant product. The most likely winner is the owner of the 'best' platform, the characteristics of which we discuss later in this section.

Despite different degrees of openness to outside complementors, various products and technologies have served as industry platforms: the Microsoft Windows and Linux operating systems; Intel and ARM microprocessor designs; Apple's iPod, iPhone, and iPad designs along with the iOS operating system; Apple's iTunes and App Store; Google's Internet search engine and Android operating system for smartphones; social networking sites such as Facebook, LinkedIn, and Twitter; video game consoles; and the Internet itself. We can even view payment technologies, ranging from credit and debit cards to micropayment schemes, as platforms that enable different types of financial transactions.

Early research on industry platforms and their innovation ecosystems generally focused on computing, telecommunications, and other information-technology intensive industries. For example, Bresnahan and Greenstein (1999), in their study of the computer industry, analyzed platforms as a bundle of standard components around which buyers and sellers coordinated their efforts. West (2003) defined a computer platform as an architecture of related standards that allowed modular substitution of complementary assets such as software and peripheral hardware. Gawer and Henderson (2007) described a product as a platform when it is one element or subsystem of an evolving technological system, when it is strongly functionally interdependent with most of the other components of this system, and when end-user demand is for the overall system, so that there is no demand for components when they are isolated from the overall system.

Taken together, these studies suggest several generalizations with regard to what makes for the best industry platform and how this can affect competitive dynamics as well as innovation at the ecosystem level. Positions of industrial leadership are often contested and lost when industry platforms emerge, as the balance of power between assemblers and component-makers changes. At the same time, industry platforms tend to facilitate and increase the degree of innovation on complementary products and services. The more innovation there is on complements, the more value it creates for the platform and its users via network effects, creating a cumulative advantage for existing platforms: As they grow in adoption, they become harder to dislodge by rivals or new entrants, with the growing number of complements acting like a barrier to entry. The rise of industry platforms may also raise complex social welfare questions regarding trade-offs between the social benefits of platform-compatible innovation versus the potentially negative effects of preventing competition on overall systems.

It follows that the design principles or 'design rules' for industry platforms overlap somewhat with those for product and supply chain platforms, but go beyond them to serve a larger purpose. For example, the stability of the platform architecture is still essential, but there are important differences. In contrast to what happens for product and supply chain platforms, the logic of design for industry platforms is inverted. Instead of a firm being a 'master designer' or assembler, here we start with a core component that is part of an encompassing modular structure, and the final result of the assembly is either unknown *ex ante* or incomplete. In fact, for truly successful industry platforms, the end-use of the end product or service does not seem to be fully predetermined by the platform owner. This creates unprecedented scope for innovation on complementary products, services, and technologies. The situation simultaneously evokes the fundamental question of how incentives (for third-parties) to innovate can be embedded in the design and governance of the platform.

This leads to another apparent design rule for effective industry platforms: The interfaces around the platform should be sufficiently 'open' to allow outside firms to 'plug in' complements as well as innovate on these complements and make money from their investments. Although this resonates well with research on open innovation, recent research on platforms highlights the complex trade-offs between 'open' and 'closed' (Greenstein, 2009). This research suggests that, while opening up interfaces should increase complementors' incentives to innovate, it is important to preserve as proprietary some source of revenue and profit. It therefore adds a more subtle take on the literature on open innovation that had extolled the simple benefits of opening interfaces.

Specific strategic questions also arise in the context of industry platforms. For example, Gawer and Cusumano (2008) argue that not all products, services, or technologies can become industry platforms. To perform this industry-wide role and convince other firms to adopt the platform as their own, the platform must (1) perform a *function* that is essential to a broader technological system and (2) solve a *business* problem for many firms and users in the industry. While necessary, these conditions alone are still not sufficient to help firms transform their products, technologies, or services into industry platforms, nor indicate how platform leaders can stimulate complementary innovations by other firms, including some competitors, while simultaneously taking advantage of owning the platform.

One particular managerial challenge is that platform leaders and competitors must navigate a complex strategic landscape where both competition and collaboration occur, sometimes among the same actors. For example, as a technology evolves, platform owners often face the opportunity to extend the scope of their platform and integrate into complementary markets. This creates disincentives for complementors to invest in

innovation in these complementary markets. Farrell and Katz (2000) identified the difficulty for platform owners to commit, not to squeeze, the profit margins of their complementors. Gawer and Henderson (2007) show how Intel's careful selection of which complementary markets to enter (the connectors) while giving away corresponding intellectual property allowed the firm to push forward the platform/applications interface. Intel thereby retained control of the architecture at the same time it renewed incentives for complementors to innovate 'on top of' the newly extended platform.

Another challenge is that, as technology is constantly evolving, platform leaders need to make business decisions and technology or design decisions in a coherent manner. For example, consider a firm that designs open interfaces to its platform: this will stimulate innovation on complements, and the firms that will act as complementors by designing these complements need therefore to be treated by the focal firms as allies, not potential competitors. This will mean that the focal firm should probably refrain from entering as a competitor in complementors' markets if it wishes to sustain the complementors' incentives to innovate. This need for coherence across business decisions and technological design decisions can be difficult to achieve since these decisions are often made by different teams within the organization. The coherence imperative requires top management's awareness of the interdependencies between these decisions, and the right product process in place to allow ongoing coordination across functional silos. Hence, to make the whole greater than the sum of the parts, we can see the need in many complex systems industries for one firm or a small group of firms to act as a 'platform leader' (Gawer and Cusumano, 2002).

Network Effects and Multisided Markets

Perhaps the most critical distinguishing feature of an industry platform compared to a product company platform or supply chain is the potential creation of network effects. As mentioned earlier, these are positive feedback loops that can grow at exponentially increasing rates as adoption of the platform and the number of complements rise. The network effects can be very powerful, especially when they are 'direct' (sometimes called 'same-side') between the platform and the user of the complementary innovation and reinforced by a technical compatibility or interface standard that makes using multiple platforms ('multihoming') or switching from one platform to another difficult or costly. For example, VHS tapes and Windows or Apple iOS applications only work on compatible devices. Facebook and LinkedIn users can only view profiles or send messages within their groups. The network effects can also be 'indirect' or 'cross-side,' and sometimes these are equally or even more powerful. Indirect effects occur when, for example, advertisers become attracted to the Google search engine or to Facebook because of the large number of users. Companies can also innovate in business models and find ways of charging different sides of the market to make money from their platform or from complements and different kinds of transactions or advertising (Eisenmann et al., 2006).

In parallel with the strategy literature, some researchers in industrial organization economics have begun using the term platform to denote markets with two or more sides, and potentially with network effects that cross different sides. Such a 'multisided market' provides goods or services to several distinct groups of customers, all of whom need each other in some way and rely on the platform to mediate their transactions (Evans, 2003; Rochet and Tirole, 2003, 2006; Parker and Van Alstyne, 2005). While the concept of a multisided market can sometimes apply to supply chain platforms as well as industry platforms, it does not entirely conform to either category. Nonetheless, there are important similarities between industry platforms and multisided markets. Among the similarities are the existence of indirect network effects that arise between two different sides of a market when customer groups must be affiliated with the platform in order to be able to interact or transact with one another (Armstrong, 2006; Rochet and Tirole, 2003, 2006).

At the same time, not all multisided markets are industry platforms as we describe them in this article. Double-sided markets where the role of the platform is purely to facilitate exchange or trade, without the possibility for other players to innovate on complementary markets, seems to belong to the supply chain category. A multisided market that stimulates external innovation could be regarded as an industry platform. However, while all industry platforms function in this way, not all multisided markets do. For example, dating bars and Web sites, a common example used in the literature, are double-sided markets in that they facilitate transactions between two distinct groups of customers. But there need not be a market for complementary innovations facilitated by the existence of the platform.

The literature on double-sided markets is particularly useful to understand the 'chicken-and-egg problem' of how to encourage access to a platform for distinct groups of buyers or sellers. Nonetheless, the literature has limitations as platform research. For example, it takes for granted the existence of the markets that transact through the platform. With the notable exceptions of Parker and Van Alstyne (2005) and Hagiu (2007), this literature has delivered only limited insight into *why* such platforms come into existence in the first place: the drivers of platform emergence and evolution. Most research focuses on pricing as the key to encouraging access and adoption. However, Evans (2009) focuses on start-up platform strategies, while Hagiu (2007), Eisenmann et al. (2009), and Boudreau and Hagiu (2009) focus on the importance of nonprice mechanisms for the governance of platform ecosystems. They suggest, in accordance with Gawer and Cusumano (2002), that pricing alone cannot be the answer to the inevitable strategic questions of platform dynamics, such as how to share risks among members of an ecosystem. These papers take double-sided (or multisided) research to the next level and bridge the strategy and product design literature as well as the industrial organization economics literature.

Managerial Implications and Further Research

There is considerable research to date on how firms can manage the process of platform leadership. In particular, companies that wish to tap into the innovative capabilities of

an external ecosystem need to develop a vision for their platform and build a sufficiently open and modular platform architecture to facilitate third-party innovation. They need to build a vibrant coalition and carefully manage ecosystem relationships that are mutually beneficial for participants. They need to continue evolving the platform and the ecosystem to remain competitive over time. Overall, managers must make a series of technological decisions on the one hand and strategic business decisions on the other, in a coherent manner.

Yet there are still several aspects of platform strategy and industry dynamics that we do not well understand. For example, in this article, we implied that some industry platforms may emerge from product platforms, but this is only a suggestion from a few cases and needs much more research. Economists tend to assume that platforms already exist and generally do not address this issue, whereas scholars of technological change, competitive dynamics, and organizational processes are more interested in change over time and could help explore more in depth the emergence platforms and associated ecosystems (Adner and Kapoor, 2010). In addition, empirical researchers such as Le Masson et al. (2009), whose focus is on collective design processes for developing industry platforms, might offer other useful theoretical and methodological perspectives.

A related and important area of further study is that business ecosystems. The networks approach from the organizational literature, by bringing its insights on network dynamics and field evolution as well as strategic networks is well positioned to make significant contributions to the question of how business networks appear and evolve. For example, recent work by Nambisan and Sawhney (2011) explicitly examines the link between platform leadership and orchestration processes in network-centric innovation. The new institutional literature rooted in sociology, which offers concepts such as legitimacy, collective identity, and institutional work, can be useful as well to examine whether and how platform leaders can successfully establish themselves as trustworthy brokers (Gawer and Phillips, 2013).

Finally, we need to expand our understanding of the impact of platforms on innovation and competition. In the economics, innovation, operations management, and strategy literature, scholars associate technological platforms with a positive impact on innovation. The positive effect stems from the fact that, by offering unified and easy ways to connect to common components and foundational technologies, platform leaders should help reduce the cost of entry in complementary markets, and provide demand for complements, often fueled by network effects. Platforms therefore offer a setting where it is in the interest of private firms to elicit and encourage innovation by others. However, concern over the dominant positions that platform leaders such as IBM, Microsoft, Google, Apple, Cisco, and Qualcomm can achieve has raised awareness that platforms may have a potentially negative effect on competition and possibly on innovation. Specific platform design approaches might also limit innovators to particular approaches which may be platform-enhancing, rather than platform-destroying. Platform leaders have the incentives and the power to encourage ecosystem innovation that is platform-enhancing, but can also act in ways that discourage or increase the cost of innovation that may be either competing with the platform, or create possible substitutes to the platform. We need further research to evaluate the impact of platform leadership, such as maintained through platform interfaces and architecture control, on different kinds of innovation. This type of research would likely highlight the potential trade-offs between innovation on modules and discrete products versus innovation on systems and platforms at the industry level.

Abstract

Business Process Outsourcing (BPO) is a relatively new global industry. In 2011, worldwide spending on BPO services totaled $153 billion (USD) and it is one of the largest and fastest growing outsourcing activities. The business is driven by firms in developed countries looking to save costs by outsourcing work to lower-wage developing countries. A number of developing countries with highly skilled labor force have benefited from the rise of the outsourcing industry. This article focuses on the case of India, the most successful outsourcing destination for BPO services. We look at the development of the BPO market and firm-level outsourcing decisions. Then, we turn our attention to India's BPO industry, considering both the drivers of growth and the organizational features.

Introduction

Business Process Outsourcing (BPO) is the outsourcing of a firm's internal back-office business functions. Outsourcing is the general term used when a firm contracts out specific operational tasks to another firm or person; this comprises of a wide range of activities such as IT software outsourcing, engineering research and development, and outsourced software product development. In the case of BPO, noncore business operations that are necessary for a firm's functioning are outsourced, such as human resource (HR), finance and accounts (F&A), and data entry. Further, when firms (usually in developed countries) decide to relocate processes to another country (usually to developing countries), this is known as offshoring. Traditionally, the primary motivation for outsourcing has been to take advantage of labor cost arbitrage. However, in more recent times, outsourcing is driven by sophisticated service offerings, higher labor productivity, and better service quality.

Over the past few decades, outsourcing and offshoring of services increased dramatically. As of 2011, worldwide spending on software products, IT, and BPO services totaled greater than $1.7 trillion (USD). Global spending on BPO services alone was $153 billion (USD) and is one of the fastest growing segments of the overall offshoring market (NASSCOM, 2012, p. 26). A number of developing countries with highly skilled labor forces have benefitted from the rise of the outsourcing industry, the most well-known case being India. While other countries like China, Philippines, and Czech Republic made headway into this market, India remains the leading destination for global outsourcing, capturing 58% of global market share (in 2011) (NASSCOM, 2012: p. 40). For this reason, we shall mainly focus on India's BPO industry.

We start off by providing a general overview of the BPO sector, looking at its historical development and considering the outsourcing decisions from the client firm's perspective. We then turn our attention specifically to India's BPO sector, looking at both the drivers of growth and understanding the organizational features of this industry.

Development of BPO Sector

The recent phenomenon of services outsourcing has similar features to the manufacturing outsourcing of the 1970s and 1980s. In the case of manufacturing sector, as labor costs increased in the West, firms sought to reduce costs by offshoring low-skilled work to low-wage countries. What emerged was a disaggregated, often modularized, value chain, whereby product development and R&D took place in different locations from where goods were produced.

The outsourcing of the manufacturing sector was successful and accelerated throughout 1970s and 1980s. At the time, services outsourcing was considered to be less feasible as they were localized, nontradable, and nonstorable. Despite offshoring of software services starting as early as the 1970s by US firms to India, Ireland, and Israel (Dossani, 2004), firms still viewed business processes as a fixed cost. These were, therefore, never scrutinized in cost-saving exercises. However, all these changed with technological advances and the arrival of the 'digital age.' Digitization allowed information to be stored and easily shared between different entities (Dossani and Kenney, 2007). Coupled with lower data-transfer costs as a result of improvements in IT and communications, firms turned to reorganizing processes to cut costs. Furthermore, processes that were digitized allowed these to be removed of location constraints. Consequently, as in the case of manufacturing, processes were separated and modularized, allowing firms to find the most cost-effective way of performing individual tasks, even if they were separated spatially.

Originally, Western firms relocated their noncore business processes from higher-cost urban areas to lower-cost small towns and rural locations. Here firms found labor and land cost savings to total 20–30% less than if they set up in urban areas (Dossani and Kenney, 2007). With low costs and higher productivity, firms continued to engage in intranational outsourcing. Although initially the pool of adequately skilled labor was enough to generate these savings, labor shortages in these areas began to emerge over the 1980s and 1990s and firms sought out alternatives sources of low-cost skilled labor.

During this period, a number of low-wage English-speaking countries started undertaking simple processing work. For example, some Caribbean nations started processing airline tickets and credit cards for multinational companies (MNCs), while in the 1980s, airlines began to fly ticket stubs to Ireland and India for processing (Dossani and Kenney, 2009). Although the scale and number of employees in these operations were small, it gave rise to MNCs and firms experimenting and relocating all kinds of business process aboard.

As improvements in technology and further digitization occurred, the pace of outsourcing business services accelerated throughout the 1990s. Firms were no longer constrained by geographical factors, and instead made decisions based on labor skills and cost. Initially, BPO to other countries started with simple, routine work such as call centers, F&A, and other work that could be done remotely. As time went on, firms began to experiment with a range of other back (and front) office services to English-speaking countries characterized by a well-educated but low-cost labor force. Countries such as India, Malaysia, China, Ireland, and Philippines all emerged as contenders for this outsourcing business. As the outsourced country becomes more familiar with the nature of the work, not only did firms outsource more processes but they also began to transfer higher value-added work.

Hence the advancement of technology and digitation of information created a huge potential for a wide range of business process services to be offered remotely. Firms moved from intranational outsourcing to offshoring to lower-waged countries. As firms and outsourced countries become more familiar with the nature of the work, BPO provisions continue to expand and accelerate.

BPO and Firm-Level Decisions

In this section, we look at some of the decisions the outsourcing firm has to consider when thinking about offshoring business processes. As the main motivation for offshoring rests on cost cutting and higher productivity, firms have to make the right choices about the kinds of work to be outsourced; otherwise it could potentially end up being a costly exercise. Factors such as what processes to outsource, where to relocate, whether processes can be separated and modularized are important considerations for successful outsourcing. We now discuss some of these factors in further detail.

The most important decision for firms is to deliberate on what processes to outsource. The simplest tasks get outsourced first as these are the easiest to manage and have lower risk in experimentation and failure. Furthermore, simple tasks allow the outsourced country to catch up and dynamic learning to take place. The rate of learning in the outsourced country depends on its knowledge base, education and skill levels, entrepreneurial spirit, and the local managers (Dossani and Kenney, 2007). The faster the rate of learning, the more potential the outsourced country has for higher value-added work. For example in insurance claims processing, Indian operations initially started off by simply processing claims; as learning took place, these operations took over the role of valuation and investigations of claims, thereby moving up the value chain of work.

Closely related to a firm's decision on what processes to outsource is the knowledge component of the process. The higher the knowledge requirement of the process the more worried the firms, may be about whether the quality of the services will change or even decline as work is transferred to the outsourced country. Any disruption to the business process should be minimized or could prove to be a risky undertaking. This is often the reason why simple tasks are outsourced initially, as both the outsourcing client and vendor firm get comfortable with the overall process.

While lower labor cost is an important factor for relocation of business processes, firms must make decisions on where to locate and the scale of BPO offered. For example in relocating to India, firms benefit from a large pool of college-educated workforce, making recruitment relatively quick. If firms want to expand, Indian operations have the capacity to increase BPO provisions without labor shortages. Thus, the scale of BPO offering in the outsourced country is significant for firms. In addition to this, firms may wish to set up within clusters where work of similar nature is being conducted. The advantage for outsourcing firms is that learning and knowledge spillovers may take place and therefore business process can be offshored faster. Outsourcing firms entering such an environment also benefit from a supportive infrastructure such as good telecommunications facilities or large pools of labor all working on similar operations.

Fourth, firms have to separate and modularize processes such that they are ready for outsourcing. In some cases, it is relatively easy to offshore the process as a whole as activities may be fairly standardized and routinized. For example, in customer care, the process as a whole can be outsourced and offshored as it does not require proximity to the firm. However, not all business processes are straightforward; usually, the ability to outsource work depends on the ability to separate each individual stage of the process. If the business process is not straightforward, firms may need to experiment or reengineer current processes to allow outsourcing to take place. The potential here is great: discarding or reformulating legacy practices and incorporating new methods mean that firms are likely to experience higher productivity brought about by experimentation and new business models.

Finally, there may be some processes that are time sensitive with specific deadlines, for example overnight medical transcriptions that need to be processed for the next day. In this case, firms may choose to offshore to locations that accommodate these time deadlines. For example, as India is 12 h ahead of United States, work that needs to be done overnight in the United States can be completed during the day in India hence shortening the turnaround time.

Drivers of the Indian BPO Sector

So far, we focused on outsourcing decisions and motivation from the individual firm's perspective. We now turn our attention to the BPO sector from the perspective of the outsourced countries, i.e., countries that are receiving outsourcing work. While this industry has taken off in a number of countries, India has emerged as the leading recipient of outsourcing. For this reason, we shall be concentrating on India's BPO

industry for the remainder of this article. In 2011, India captured 58% of market share of global sourcing work, while BPO export earnings totaled over 15 billion (USD) in 2012 (NASSCOM, 2012: p. 102). India has a number of key advantages for firms looking to relocate and outsource business processes. In this section, we shall outline some of the key drivers of the Indian BPO industry.

First and arguably the most important input for BPO industry is a well-educated labor force. Unlike outsourcing of low-end manufacturing jobs, service relocation requires much higher skill levels. In the case of low-end manufacturing outsourcing, labor force can be relatively low skilled since the skills can be embedded in sophisticated machinery. Therefore, a developing country has access to a large portion of its population with the ability to engage in the manufacturing process. However for the production of business services, skill levels must be relatively high and a country must have a ready pool of labor to perform tasks established by the outsourcing firm. In the case of India, the BPO sector has benefited from a large well-educated English-speaking population, allowing a continuous pool of skilled workers for this sector. In 2012, India's BPO industry alone directly employed 880 000 workers and indirectly employed an additional 3.5 million people (NASSCOM, 2012: p. 117). Furthermore, India's BPO operations initially developed in large metropolises like Bangalore, Mumbai, and Delhi, attracting a large number of potential employees and ability to expand operations. Hence, unlike the early relocation of services to rural areas in the West, where skilled labor shortages was the main constraint to expansion, locating in large Indian cities ensured continuous labor flows.

Currently, India is experiencing an interesting shift in the location of its operations. Although service provision continues to grow in traditional locations (like Bangalore, Mumbai, Delhi), we observe the rise of secondary and tertiary cities as alternative service delivery locations. As pressure on labor costs as well as infrastructure cost (real estate, transportation) mount, Indian operations look to these locations as a way of keeping cost low. These secondary and tertiary cities, like Bhubaneswar, Jaipur, and Chandigarh, have access to a large skilled workforce with lower infrastructure costs and state government support, delivering significant cost advantage for firms (NASSCOM, 2011, 2012). Furthermore, the growth of these secondary/tertiary cities indicates that India has significant capacity for expansion, if BPO business continues to develop. For India, the emergence of these alternative service delivery centers mean that firms can keep costs low and fight off competition from other emerging centers in China or Philippines.

In the past 30 years, advances in technology and communications have brought about revolutions in many industries, overhauling processes like never before. It is no doubt that these technological advanced have contributed greatly to the development of the BPO sector. Digitization allowed information to be shared across borders, while the declining costs of data transfer and the 'proximately' to places like India, allows companies to benefit from labor cost arbitrage. Yet, Indian BPO expansion has not relied solely on technological change. As in the case of software outsourcing, it was important to demonstrate that BPO was a legitimate and normal business decisions for firms. In Indian software outsourcing, firms obtained international certification (such as International Standards Organization (ISO) certification; Carnegie Mellon software certification) (Dossani and Kenney, 2007). However in the BPO industry, legitimacy was provided by the huge success of early adopters of service outsourcing. Entry by large MNCs in India started in 1993 by American Express, followed by British Airways in 1996, and General Electric in 1998. It was not until the early 2000s that a whole host of fortune 500 firms, such as HSBC, Hewlett–Packard, Citicorp, all relocated their business processes to India (Dossani and Kenney, 2007). By this time, firms looking to cut costs saw this as a part of a viable business decision.

Traditionally BPO work in India started off by firms undertaking voice-based services such as call centers or data entry work. This was followed by more generic back-office functions such as HR and F&A. As Indian service providers established a strong offshore business, they gradually moved up the value chain. More recently, as these traditional markets matured and cost savings on the margin start to diminish, Indian firms began to reengineer processes to move into higher knowledge-based work. This process of moving up the value chain has been vital for the survival of the BPO business in India, generating a huge growth potential in this sector. Indian firms have shifted their focus from simply providing generic support services to providing higher value-added activity in specific industries.

This shift toward knowledge process outsourcing is seen as a natural progression for BPO firms. Driven by better analytical tools, huge volumes of data, and better understanding of specific industry processes, Indian operations are now looking to provide high-end services such as legal process outsourcing, knowledge management services, or research and analytics to both existing and new clients. This is evident from the fact that data analytics is the fastest growing sector in India after financial services (NASSCOM, 2012: p. 117). As BPO firms move from generic to more specific outsourcing work, firms need to reengineer processes toward industry specific operations. As Indian BPOs offer higher-end processing services, their success will depend upon whether they are able to develop capability across the entire value chain. One strategy for BPOs to quickly obtain industry specific expertise is to acquire smaller niche, specialist companies to fill in the knowledge gap. By engaging in mergers and acquisitions (M&A) activities, BPO can offer far more varied service offerings and extend market reach. This new development in the BPO market suggests Indian firms are far more likely driven by value creation services than simply relying on cost arbitrage alone.

Furthermore, India's goal to be the leading provider of services is not restricted to its own borders. As India moves up the value chain, some lower end work is being outsourced to cheaper countries, prompting the rise of Indian MNCs. The emphasis on a 'Global Delivery Model' has become an important feature for the larger service providers. The idea is to provide services using a team that is globally distributed. In doing so, clients are offered services that are seamlessly delivered from global locations to the local markets, providing continuous 'round the clock' services. Furthermore, clients can enter local markets easily and take advantage of local knowledge, language, and culture in a particular country (PWC,

2011). The major advantage for the Indian BPO firms is the ability to access resources of varying costs across different operations. Firms can 'pick and choose' where individual process should be done, mixing costlier 'on-site' resources with cheaper 'offshore' components. This allows firms to deliver services to its customers at optimal costs and the ability to remain competitive. Finally, by going global, Indian operations are 'risk-proofing' from major disasters, either natural (flooding, earthquakes) or man-made (political instability). In the event of a disaster, service delivery for clients can be easily shifted to another location hence not disrupting business. The 'Global Delivery Model' has been successfully implemented by some large software and service providing firms such as TCS and Infosys. In 2008, the delivery footprint of the Indian BPO industry extended to over 25 countries outside of India, increasing their global presence (NASSCOM-Everest, 2008).

While India's labor pool, higher value-added work and its eyes on global markets are the more contemporary drivers of the BPO industry, there are of course a whole host of other contributing reasons for its success. Long-term factors such as low geographical, political, and data security risk; good government support; and excellent infrastructure provisions all contribute to the Indian BPO success. The reforms of 1991 and subsequent liberalization of India brought about two important changes to business in India. Firstly, the state-run telecommunication sector was reformed by allowing competition from large numbers of private providers into the market. These telecommunication firms could bid for a wide range of contracts from niche specialization to fully integrated services. As a result, India ended up with telecommunication networks with quality and cost levels on par with developed countries. Secondly, as foreign venture capital rules were changed, this led to the availability of financial support for Indian start-ups including those emerging in the provision of business services (Dossani and Kenney, 2007).

India currently remains the world's leading outsourcing base (in both IT and BPO); however, other countries such as China, Philippines, and Czech Republic are also emerging as major outsourcing destinations. The survival of Indian BPO firms depends on the ability to expand offerings and capture more of the value chain. This will require further experimentations, new business models, and focusing on reengineering processes. Indian firms are also looking to expand into new markets. Traditionally, with India's strength in English, English-speaking regions form the bulk of export, the UK and US market accounting for over 80% of BPO exports. However, Indian firms are venturing into newer markets through acquisitions, enhancing language capability and setting up global delivery centers in Eastern European, Asia Pacific, and BRIC (Brazil, Russia, India, and China) regions. As Western markets are currently economically depressed, it is no surprise that Asia Pacific and BRICs (including India itself – see below) have seen the fastest growth rate for Indian BPO organizations in recent years (NASSCOM, 2012).

Finally, as India is one of the largest economies in the world and experiencing high economic growth despite global uncertainties, Indian BPO firms can look to its own domestic market to provide services. As BPO operations move into niche, specific markets and the types of services expand, BPO firms can target domestic firms to provide servicing solutions. The domestic BPO segment is expected to reach 149 billion (rupees) driven mainly by voice-based services (particularly local language provisions) and other niche services. Hence domestic demand may be one future driver of the Indian BPO business.

Organizational Structure of the BPO Industry in India

Although the growth of the BPO industry in India was initially triggered by MNC subsidiaries, over time the market has evolved and with it the organizational structure has changed. In India, there are over 500 BPO organizations across various industries, all differing in size and diversity in service offering (NASSCOM, 2012). In addition to this, a wide range of ownership and organizational structures exist. Dossani and Kenney (2007) identify seven organizational structures featured in the Indian BPO market: MNC subsidiaries, MNC outsourcing service providers, MNC specialist, US high-technology start-up, Indian specialist, Indian independents, and Indian IT industry subsidiaries, which we will discuss next.

MNC Subsidiaries

As mentioned earlier, MNC subsidiaries were the first movers in the Indian BPO market. American Express established the first back-office BPO operation in 1993, followed by British Airways in 1996, and General Electric in 1998. Since 2000, a whole host of global firms entered into this market, across different industries. Even MNCs such as Dell computers, AOL, and SAP with no previous Indian operations were successful in establishing BPO operations. Furthermore, BPO provision was a natural progression for MNC subsidiaries that already had software development facilities in India.

By setting up an internal operation, MNCs benefit from greater controls over key business decisions such as labor processes, business organization, and ability to keep sensitive information in-house. As the MNC subsidiary gains substantial experience with BPO work and organizational process become easier with time, MNCs can outsource higher value-added work with lower risk, allowing the subsidiary to handle increasingly sophisticated work on par with their Western counterpart. Today there are more than 100–120 MNCs in India and about 30% of these businesses are focused on delivering high-end services such as research, analytics, consulting, and legal services (NASSCOM, 2012).

Higher value-added work is not the only indication of maturity of the Indian subsidiaries. MNCs handing over global managerial responsibilities to their Indian subsidiaries show confidence in the quality of Indian operations, as they are trusted with enforcing standard operating practices in other overseas facilities. Finally, in some cases, the Indian subsidiary is successful enough that the MNC feel its subsidiary can become an independent service provider to other third parties. For example, Genpact, which initially started off as a business process subsidiary of General Electrics is now an independent company offering BPO solutions (Dossani and Kenney, 2007).

MNCs benefit from operating a subsidiary as it is able to control the business operations internally, reduce risk

associated with knowledge transfer, and expand service offerings relatively easily. As more MNC subsidiaries have entered the Indian market, the BPO sector continues to evolve. Indian subsidiaries are carrying out more sophisticated work, enjoy greater management responsibility, and in some cases the Indian operations can spin off as an independent company. It is expected that MNC subsidiaries will continue to set up and expand in India.

Multinational Outsourcing Service Providers

MNC outsourcing service providers are no strangers to outsourcing globally. Many companies like IBM, HP, and Keane (data systems firms) or ADP, EDS (payroll and accounting) offered service solutions internationally, prior to the rush of outsourcing to India in 2000s. After 2000, many of these firms entered the Indian market due to competition from the Indian independents and the demands for lower cost from customers. By locating in India, MNC outsourcing service providers were able to deliver nearshore and offshore services, at a lower cost base. These companies were able to enter the Indian market quickly and scale up operations rapidly. While MNC outsourcing providers had long established customer relationship and experience of offshoring, entering India was a response to cost and delivery pressures.

MNC Specialist

It is not only the large sized MNC companies that can benefit from outsourcing to India. Smaller MNC companies that offer niche and varied specialization may also move into the Indian market to access high skilled, cheap labor. MNC specialists undertake a wide range of processes from medical transcription, tax preparation, map digitization, engineering drawing, and so on. Often these MNC specialists may have little experience in operating abroad, yet it makes sense to outsource labor intensive, highly specialized work as this is often more expensive in a developed country.

US High-Technology Start-Up

The traditional model of start-up companies is one where a firm begins in a single location and only offshores operations as it matures. However, there are advantages for start-up companies to consider offshoring in the early stages of its development. Firstly, start-ups are often constrained by limited resources; therefore, offshoring can supplement onshore operations, at a much lower cost. For example, after the dot.com bust in the early 2000s, high-tech companies were forced to operate at lower cost, as financing was a major issue (Dossani and Kenney, 2007). Secondly, by offshoring at an earlier stage in the business model, firms can experiment at a much lower cost. Experimentation is important for businesses, particularly at early stages of operations. Hence by offshoring early on firms can conduct more experiments then they would otherwise. Alternatively, start-up companies can locate their headquarters, marketing, and sales in the United States and all other operations in India (including R&D). For Indian firms, not only does this create further employment opportunities, but they also benefit from knowledge spillovers and experience in high-technology entrepreneurship.

Indian Specialist

Unlike the software industry in India, the impact of the Indian specialist firms in nonsoftware service sector was less significant. Initially, Indian firms suffered from a lack of legitimacy, customer contact, and domain knowledge. However, as Indian firms gain experience with service outsourcing, the number of Indian specialist firms grew. Labor cost arbitrage is not the only reason companies' relocated work; Indian specialist quickly gained recognition for high skilled, high value-added work. As a result, the Indian BPO sector consists of large numbers of niche firms engaged in a wide range of service provision, across a variety of industries.

Indian Independents

Indian independents are like the Indian specialist but focus on providing general services like call-center operations or claims processing. These firms tend to be much larger than the Indian specialist, some employing more then 6000 employees and may have large MNCs as customers. The growth of these large Indian independent firms accelerated after the dot.com bust as US firms looked to reduce costs. For example, Tracmail was established to provide back-office services to US firms such as Amazon and Yahoo! (Dossani and Kenney, 2007). From 1999 to 2004, the rapid expansion of low-end service work, such as call centers, brought about many benefits to the Indian market; however there were a number of problems with this kind of work. High attrition rates, lack of career path for employees, cut-throat pricing, training expense, and problems of working through the night (Ramesh, 2004) encouraged Indian Independent to undertake higher value-added BPO work. As the nature of the BPO work means that business activities are part of a larger process, firms have the opportunity to move up the value chain as they become familiar with process. As a result by 2004, Indian independents were diversifying away from call centers into other business areas such as F&A.

As the market in India consolidates, M&A activity in recent years has increased for both the Indian independents and Indian specialist (NASSCOM, 2012). Indian independents are often brought over by MNCs looking to set up in Indian or large capture-all firms looking to provide 'bundle offerings.' The BPO market is likely to be dominated by these larger, diversified firms with multiple service offerings, as smaller firms are often overlooked for large contracts both domestically and internationally.

Indian IT Industry Subsidiaries

As early as 1970s, Indian software service subsidiaries were the initial trigger for the relocation of services to India, even before BPO took off. These companies initially grew by using low-cost Indian labor to provide high-quality software provisions globally. Over the last few decades, Indian software service vendors developed into large globally competitive firms, with significant global market share; companies such as TCS,

Infosys, Wipro, Satyam Computers, and HCL are leaders in software outsourcing. These companies are all experienced with operating on the global level, managing foreign customers, with excellent executive and managerial capabilities, and the ability to get overseas contracts.

The move to provide BPO was therefore a strategic opportunity for Indian Software firms as they acquired significant advantage over new entrants in the BPO market. Once they decided to provide business-processing services, these software firms took different routes to enter the market. Some grew organically; others established in-house subsidiaries or through M&A activities. While Indian software firms were leaders in the provision of software services, many found the nature of BPO provision somewhat different from software provision. Particularly, the skills and requirements of the workforce in BPO differed from software workers who were mainly from science and engineering backgrounds. BPO workers often possess qualities such as good interpersonal skills, the ability to directly deal with customer interactions, and were often with a social science or commerce background. Hence, while it is natural to assume Indian software subsidiaries would have been the most successful in providing BPO service, in reality these firms had to act strategically and reorganize processes to enter the BPO industry. For example, rather then moving into simple call-center service provisions (and recruiting a large number of call-center staff), Infosys established an in-house subsidiary, Progeon (now known as Infosys BPO Limited). Progeon focuses on only providing high-end back-office work, utilizing the already existing software skills of Infosys. Likewise, HCL established its in-house subsidiary, HCL BPO. The subsidiary provided call-center work by acquiring UK call centers rather then expanding in India. By locating in UK, HCL solved the language problems of Indian call-center operations and left Indian operations to concentrate on back-office work.

To summarize, we see that the BPO sector in India has a number of different organizational and ownership structures. As the economic model behind India's BPO industry is constantly changing, so too will the organizational structures of the industry. While the MNC is a large part of the BPO market and will likely to dominate this sector, Indian firms are also growing dynamically. Looking ahead, the Indian BPO market is likely to remain a high-growth industry as firms constantly evolve its service offerings and diversified into many different activities. Although India is currently still the number-one destination for sourcing, its dominance is threatened by other emerging centers like China and Philippines. Survival of Indian firms' depends on their ability to capture more of the value chain and expansion into new markets.

Abstract

Busyness (or being busy) is a phenomenon experienced by many Americans and it is a folk concept used to describe everyday life; the concept is also used by researchers describing and analyzing the pace of those lives. Busyness includes assumptions about time and its use, everyday activities, individual and family choices, and constraints on decision making. It assumes values such as performing activities that are consistent with commitments to other people, the necessity to create individual identities by adopting lifestyles, and demonstrating responsibility by being productive and efficient. Busyness was initially associated with increases or decreases in paid work, but it has increased with increases in leisure time, wages, consumption of goods and services, and unpaid work. It is a complex phenomenon that is at once individual and social, and behavioral and experiential. Facets of the concept are addressed by different disciplines and fields, and it is often associated with individual or social costs, such as stress. Information technology has been used by individuals and organizations to control and coordinate activities by providing connectivity to other people and information, although doing so may simultaneously intensify the experience of busyness.

Defining Busyness

Being busy, or busyness, can be broadly defined as having too much to do in the time available. Time is experienced as being a scarce resource and busyness may be expressed as a struggle to balance or juggle commitments, of time being 'squeezed' from the day, or of a speeding up of daily life. The concept is used both in scholarly discourse and as a folk category in everyday conversations. As a scholarly concept it includes considerations of time, activities or tasks, individuals, and context or constraint. Despite its apparent simplicity and familiarity, busyness is a complex construction that is embedded in characteristics of modernity.

Being busy is closely related to time. First, busyness is situated in historical time and it is different than working hard. Busyness seems to reflect a distinctly contemporary worldview in which activity is both ubiquitous and urgent, but also where the stakes might not be as high as sheer survival. Second, busyness is associated with clock time in which days, minutes, and seconds provide a metric for assessing and comparing use or consumption of time (Snyder, 2013). Third, claims of busyness go beyond describing how discrete activities fit into periods of time, but they also describe a state of being that defines a way of life, either that of an individual or a society. Busyness implies a time horizon or duration of time in which one is busy and, perhaps, never not busy.

Being busy also differentiates time by the activities it contains. Activities can be observed and recorded and doing so simultaneously acknowledges that the time could be used to do something else. Yet busyness goes beyond the description of activities. It has a subjective and non-observable quality; it is as private and internal as it is a matter of display. This is partially because people learn to produce and recognize distinct activities and the scripts that define how they are appropriately performed. These distinctions increase the number of activities as well as their heterogeneity. There is an important granularity to busyness, for the more distinctions made among activities and their components, the more there is to be managed (tracked, categorized, reassembled, etc.). Likewise, there is a private work of anticipating, planning, and prioritizing that is necessitated by being busy but that cannot be observed by others. Life in general or specific days do not just accelerate familiar activities, but when activities proliferate, new coordination or management tasks are created, ironically adding to busyness. This is tacit work that is both individual (individuals may define and organize tasks differently) and social, since scripts, routines, and values are learned in society.

Third, busyness implies a context or constraints in which people are acting. These constraints permit comparisons that allow people to identify themselves as busy. Constraint is important because it shifts the experiential locus of busyness from the individual to the environment in which they act. Constraints allow people to experience busyness as something that happens to them apart from the actions they take. There is a sense of fullness or of pressure to initiate and complete activities against a backdrop of fear that everything might not be accomplished. This defines the day as a set of accomplishments that should or must be completed, although what will happen if they are not is often unclear. In fact, being busy means experiencing life as both a set of accomplishments and of activities that once seemed essential, but which were not completed.

The ultimate time constraint is death. Being busy can push back thoughts of mortality by filling days with activities and it may seemingly extend life by allowing people to do and experience more in the same amount of time. Despite the seeming simplicity of being busy it is richly complex. Individuals may distinguish activities performed from the private, internal work of managing time. Evidence that they are busy may be provided by remembering tasks they desired or expected to perform but did not.

Busyness affects individual capabilities and their interactions with others. Activities and tracking them are related but distinct, and it is an individual responsibility to do both.

There is a solitary aspect of being busy, for the focus is with how efficiently individuals allocate time. The contemporary discourse of being connected identifies an emergent category of activities that requires effort and cannot be taken for granted. The busyness of others affects lives, even those of people who eschew a life packed with activities and commitments. The busyness of others is salient when daily schedules are laid and plans to undertake activities are contingent on the availability of other people.

Being busy is therefore not a mere descriptor of individual lives but also of the society in which they live. Busyness is social because what drives so many of the activities is situated beyond individual agency – government regulation, deregulation, consumerism, knowledge work, technology, etc. The sociality of busyness is deeper, however, for a modern person does not simply fit into his or her society, but from it they choose how to live: they construct a lifestyle in consort with others who are doing the same. In modern societies, there is a sense that things could be different than they are and that it is the individual's responsibility to be the author of their own life. Under such conditions, busyness assumes a moral weight (Greenfeld, 2005).

To be busy implies interpretation and judgment, as well as enumerating activities. Interpretation enters because we cannot simply watch people in order to exhaust the possibilities of their busyness, for everyone is always performing activities, even if it is sleeping or 'doing nothing.' Researchers can watch people rapidly performing diverse activities, but they might not judge themselves to be busy. Either an analyst or a cultural native proclaims that what is occurring is evidence of being busy, and there is no reason to assume that insider and outsider assessments will coincide.

Moreover, busyness itself has changed. First, busyness has historically been addressed as an issue of the relationship between work and leisure, so that it is difficult to reconcile survey results in which work paid hours are generally not increasing but individuals claim to be busier. As familiar work-life boundaries have dissolved, it is difficult to locate the causes of busyness in work hours. Linder (1970) spoke of a harried leisure class to identify precisely this disconnection of work and leisure. Accordingly, it is difficult to differentiate real and perceived busyness, just as activities and experience can be difficult to categorize as that of work and family.

Second, claims that busyness is exclusively a middle or upper class affliction are challenged when lower-income, under-employed, and even unemployed workers experience busyness. Cutbacks to social services and increasingly flexible, customizable work hours shift responsibilities to individuals and families, and results in fragmented daily schedules found across income levels.

Third, there is increased sensitivity that busyness is not a uniform, homogeneous transformation of society to one that occurs unevenly and is structured by gender. Wajcman (2008) observed that men and women enjoy different kinds of leisure time. Men's occurs in longer blocks of time and is relatively uninterrupted, while women's leisure is tied to the nature of household work and the activities of children, and it is more likely than men's leisure to be interrupted. Women's leisure may be less restorative and, in fact, simply another form of work. Although Wajcman was describing the United Kingdom, her analysis suggests that fine-grained differences in activities patterned by the domestic division of labor can produce qualitatively different experiences of time and busyness. Differential participation in labor markets by men and women, and the characteristics of particular jobs, should have these fine-grained consequences in households and in the experience of busyness by their members.

Fourth, the experiential component of busyness is essential and it cannot be inferred from quantified measures of time allocated to activities. No amount of observation can fully capture busyness since it is partially a function of subjective experience that comes from comparison to normative standards that vary culturally. Thus, busyness is descriptive and prescriptive: it is about what should or must occur during a day and tracking progress in fulfilling plans is just an additional activity.

Fifth, members of modern societies assemble their own lifestyles from resources provided by society. This work is largely individualized and further enabled by information technologies (ITs) that provide seemingly unlimited information and capacities to build networks and to 'be connected'. While this lifestyle work is liberating, it simultaneously increases individual responsibilities to forge identities, typically through activities of production and consumption. For example, advertisements that proclaim opportunities to 'have it your way' place pressure on people to think about their lives and to participate in activities that will enact them. Collectively, this lifestyle-building both adds to the public and private activities of daily life, and its individualized nature intensifies the fragmentation of daily schedules that then must be coordinated among family members, friends, coworkers, and acquaintances.

Busyness in the United States, as in any country, must be understood as one manifestation of an international phenomenon. It is grounded in modernity and explanations draw upon general theories of production and consumption (Vercruyssen et al., 2011). Accordingly, both busyness and its scholarship transcend national boundaries; it is not situated exclusively in the United States, despite the influence of pioneering contributions by Schor (1993) and Hochschild (1997).

Intellectual Backgrounds, Schools of Thought, and Advocates

Conditions that affect time use are ubiquitous and are addressed in many different fields and disciplines. Scholarship about time allocation is well developed and fundamental to comparative studies of busyness, but it does not capture all that is salient to the latter since being busy is about more than time and activities. A central challenge to the study of being busy is that much is relevant to the topic and little can be excluded, yet a core of 'busyness studies' is absent. The study of busyness is therefore more an intersection of disciplines and fields than a discrete field.

Academic Approaches

Sociology, economics, psychology, and anthropology are especially germane to the scholarship of busyness. Sociologists

contribute time allocation studies that permit cross-national comparisons and that capture trends in how Americans allocate time. Several approaches are used. In 24-h recall time diaries, individuals complete a diary about the previous day's activities. Increases in one activity must be offset by reductions in others. Analysis of activities may reflect categories (e.g., work, recreation) defined by researchers that facilitate comparison or by diarists that correspond to the distinctions they use to organize their everyday lives. Broader categories of activities may facilitate comparative research, but may not capture subtle shifts within them. The approach relies on recall of time use (not observation of behavior) and it may miss infrequent or episodic activities. The focus is on behavior rather than experience. The American Heritage Time Use Study database, for example, combines four surveys conducted by the University of Michigan, University of Maryland, and the American Time Use Survey (ATUS) conducted since 2003 by the US Bureau of Labor Statistics (http://www.timeuse.org/ahtus/).

A second approach is that of estimated activity data sets in which individuals are asked to estimate the time they spend on a sample of total activities. Advantages include a typically high response rate, precisely replicated questions that allow comparison, potentially large sample sizes, and the ability to capture infrequent activities. Limitations include informant recall bias, survey questions and categorizations of data that are not salient to local activities or discourse, attention to behavior and not experience, and data that does not capture subtle shifts in usage of time. Examples include the General Social Survey from the University of Chicago which has covered the broadest range of activities since 1972; the Survey of Public Participation in the Arts conducted by the US Census Bureau for the National Endowment for the Arts since 1982; and the Fitness Surveys by the National Center for Health Statistics since 1985.

Despite limitations for understanding busyness, time allocation studies provide the best tracking in usage of time by Americans, and the findings provide much of the data that is salient to public policy and civic discourse about the nature of contemporary society.

Economists look at time as a scarce resource to be rationally allocated by individuals and households. Time allocation data is relevant to how people choose to participate in domestic production versus working additional hours and purchasing goods and services, with time as the ultimate limited resource. The decline in hours spent cooking, for example, is correlated with women increasingly entering the labor market, thereby increasing income but not time available to prepare meals. Time allocation at least partially reflects trends in wages, and the costs of goods and services. Hamermesh (2009) suggests that economists should use time allocation data collection to explore topics such as household production and bargaining, joint time use by spouses, peer effects and social norms (including timing activities), and the relationships of macroeconomics to individual and household activities.

Psychologists view time use as a behavioral manifestation of preferences and values, specifically as it correlates with mental processes in daily life (Csikszentmihalyi and Larson, 1987). The authors' Experience Sampling Method (ESM) takes various forms, but it attempts to describe self-reported mental processes as they occur in context. Protocols may require individuals to respond at regular intervals, to random signals, or after specific events. ESM can obtain empirical data on daily activities and psychological states and patterning of thoughts, thereby providing data relevant to the experiential component of busyness. Multitasking, for example, has become a basic strategy used by many couples to perform more activities in the same unit of time. Offer and Schneider (2011) use ESM to demonstrate that men and women differ in kinds of multitasking they perform, the contexts in which they perform it, and how they assess their experiences. Krueger et al. (2008) propose a National Time Accounting that links time diaries with respondents' recalled emotional experiences of a day's activities. They approach time accounting with a focus on psychological well-being as measured multidimensionally.

Finally, anthropologists conduct cross-cultural comparisons of time use, and they situate discrete activities as components of social practices that occur in time and space. They focus on meaning and the material accoutrements of social interaction (Graesch, 2009), as well as emic (insider) perspectives on activities and time use (Darrah et al., 2007). Ethnographic fieldwork attempts to link household-level data with macro-level societal conditions. The methodology gets at fine-grained discriminations among activities as they are categorized by participants. This approach allows observed activities to be connected to how they are discussed by actors, thereby linking agency with structure, experience, and meaning. The limitations of in-depth fieldwork are the small sample sizes and lack of random sampling, as well as analytical categories that may limit comparisons.

Interest in busyness is grounded in scholarly interest, but because it addresses the fundamental question of how people spend time, it is also associated with broader societal issues and civic discourse about them. One interpretation of busyness is that of a time crunch or time famine. Based on national survey data collected 1948–87, Schor (1993) argued that Americans were overworked because, despite productivity gains, hours in paid work had not declined. The picture painted was one of trends external to individuals that forced them to undertake new tasks while simultaneously spending more time in paid work. A counter argument is that hours of paid work have not increased and any time famine has been created by individuals taking on additional work hours, in effect trading time for income that is spent on goods and services, yet another activity. Hochschild (1997) examined the time pressures felt by families as more women entered labor markets. From research she conducted in a small midwest town during summers between 1990 and 1993 on a company she calls 'Amerco', Hochschild found that while people articulated values in which family commitments were primary, they were often drawn into workplaces where they often felt more rewarded. A result was that previously distinct cultural domains of work and family became blurred as family became work and work became family.

Organizational Implications

Increased levels of worker productivity and work hours, as well as employer requirements for mandatory overtime, flexible hours, or availability to fit into corporate optimal scheduling practices can make it difficult for workers to plan other

activities. Perceived stress, increased absenteeism, and attrition may result, thereby threatening productivity (Perlow, 1997). Computer-mediated communication, such as e-mail, originally promised to enable employees to communicate quickly across time and distance. Mobile technologies allow many workers to perform at least some job-related tasks virtually anywhere, while simultaneously being constantly engaged in work and accessible. This can amplify the blurring of domains of work, leisure, and family, and it presents new responsibilities for managing time use. For example, because e-mail is asynchronous, when coupled with norms of being accessible and responsive, its stored messages can intensify feelings of work overload (Barley et al., 2011).

Current Knowledge

There are no comprehensive measures of busyness since the concept includes both behavior and experience, and because the concept is primarily of interest to separate fields and disciplines with diverse interests. Current knowledge is accordingly about the conceptualization and utility of the concept as it is about empirical findings about its extent.

Acceleration of Social Change

Busyness as a social phenomenon is distinct from hard work, and it is grounded in specific cultural milieus and historical moments (Greenfeld, 2005). Certain cultural milieus value busyness and make it a component of meaningful individual lives, as when individuals prize activity and efficiency. Historically, busyness is associated with three forms of social acceleration (Rosa, 2003). Technological acceleration results from speeding up processes of transport, communication, and production through technological innovation. IT, in particular, affects acceleration by allowing more activities to be allocated to the same period of time. Such efficiency is in turn linked to increased leisure. IT also underlies activities that are valued in themselves; gaming and many uses of social media are exemplary. These new activities in principle require time that must be taken from other activities.

The acceleration of social change is manifested in rapid changes in social organization and structure, patterns of action, and scripts for action. A result is that past experience may be less reliable as a source of lessons for the present and future. Work and family exemplify the effects of this acceleration, where families are less often multigenerational enterprises and work is no longer stable throughout an individual's life, much less across generations. Third, the pace of life itself accelerates, which is paradoxical since technology may have been adopted to provide more leisure. This pace is reflected in personal assessments of scarce time and feelings of being harried (Darrah, 2007). The acceleration is reflected objectively in contraction of time spent in activities, such as eating or walking faster, or the compression of activities and experiences within a given time period by simultaneously performing activities, and reducing pauses or intervals.

Social acceleration is driven by capitalism in which time equates to money, innovators need to be first to market, and material consumption is intense. It reflects competitive pressures on individuals to work longer hours in order to make themselves more attractive to employers and on employers to intensify work processes in order to maintain smaller headcounts in order to reduce training costs, wages, and benefits. Flexible work hours and locations, too, lead to scattered working hours and more consumption. Flexibility and a reduction in planning and formal patterns of interaction weaken sociotechnical structures and create additional tasks of coordination (Southerton and Tomlinson, 2005).

The cultural driver is created by an image of the good life as one fulfilled during the human lifespan. Social acceleration promises to produce more and diverse experiences, hopefully resulting in a fulfilling life. Such promises are especially important during historical conditions when paths to meaningful lives are uncertain.

Time Allocation

Time allocation studies sensitize us to the fact that people are always doing something; in this sense, everyone is always busy. These studies divide time into periods that contain distinguishable activities. Individuals and households then make decisions about allocating time to perform the activities. The power of the approach lies in the zero-sum nature of time: by tracking activities over the 24 h of the day, increases in any activities must be offset by reductions in others and vice versa (Gershuny, 2000). Changes in allocations reveal how individuals use time that is categorized in socially meaningful ways. The categories themselves are not immutable and their definitions tell us about how time allocation is meaningful within specific cultures. Although time allocation studies permit cross-national comparisons, the categories must be created either by observers or the people whose activities are being described. The former distinctions facilitate comparison, but at the risk of distorting how people experience and make decisions about their daily lives. The latter perspective is sensitive to how people experience and organize their daily lives, but it inhibits comparative studies.

Robinson and Martin (2009) use ATUS to describe trends in paid and unpaid work in the United States, providing the broad-brush portrait of national time allocation that underlies most discussions of busyness. First, men's time devoted to paid work (including education, training, and searching for jobs) declined from 1965 to 1985 and then remained flat through 2003. In contrast, women's hours in paid work remained flat from 1965 to 1985, increased in 1993, and then remained flat through 2003. Aguiar and Hurst (2009), too, find that the average man in 2003–05 worked 40 h per week (including commuting time), compared to 43.5 h in 1985 and 51 h in 1965 (in demographically adjusted hours). Women's participation in the labor force between 1985 and 1995 contributed to the increase in their work time. In summary, overall time devoted by men to paid work has declined; for women, it has increased.

Second, men's unpaid work increased between 1965 and 1985, and then did not change through 2003. Men performed on average two episodes of unpaid work per day, with 85–90% of men performing unpaid work on any day. Nearly 100% of women performed unpaid work each day although their total

time in it declined between 1965 and 2003, offsetting their increase in paid work. Most of the decline is attributed to women's reduced time in food preparation and the average number of episodes of unpaid work for women dropped from five in 1965 to three by 1990, where it has remained. Strikingly, total work time declined by 15% between 1965 and 1985, while leisure time increased.

Aguiar and Hurst (2009) note that leisure has increased for men and women since 1965 by 5 and 3.5 h per week, respectively, with most of the gains coming before 1985. In 1965, the average American spent 31 h in leisure activities compared to 35 h in both 1985 and 2003–05. They define leisure as including time spent watching television, socializing with friends and family members, sports, reading, hobbies, entertainment, and all similar activities. For both men and women, leisure inequality has increased since 1985. Less educated men and women have experienced substantial increases in leisure, while more educated individuals have experienced few leisure gains. Men with at least 16 h schooling spend less than 100 h per week in leisure activities, while men with 12 years and those with less than that spend, respectively, 108 and 113 h. The increase in leisure inequality corresponds to documented increases in wage and consumption inequality (Aguiar and Hurst, 2009: pp. 57, 61).

A contribution of time allocation studies then is that being busy is not simply a function of time at paid work. Americans perceive that they rush more and are more stressed, despite the decline in hours at work, although it is also true that the mean minutes on break at paid work declined significantly for both men and women between 1965 and 2003 (Robinson and Martin, 2009). While differences in reporting activities may be a factor, the results suggest that time pressure during paid work may have intensified.

Hamermesh and Lee (2007) compare data from Australia, Germany, the United States, and South Korea. Just over 42% of US men (42.6%) and 54.5% of women report they are 'almost always' or 'often' under time pressure. Their analysis suggests that the celebrated time crunch better characterizes higher-income families both because their members choose to work more hours and because they have higher incomes to spend during the same amount of nonwork time. This result is consistent with Linder's argument (1970) that increasingly specialized work leads to productivity gains that result in products and services that have to be consumed, thereby intensifying the pace of consumption, the demand for higher quality goods and services, and their simultaneous consumption.

The time crunch debate frequently assumes that being busy is harmful by equating it with being harried or stressed. Yet busyness may simply provide a neutral descriptor of contemporary life. In fact, being busy or experiencing time pressure may be partially explained as a culturally acceptable way to account for everyday experiences in societies dominated by modern industrial values. Even when complemented by assessments of quality of life, it is difficult for time allocation studies to capture the complex contexts in which seemingly discrete activities occur and the coordinative work that permeates daily life and binds together presumably separate domains of paid work, unpaid work, and leisure. This is not to discount the significant contributions of time allocation research, only to point out that allocating activities to time captures an important, but not determinative component of busyness. Likewise, efforts to directly link activities with perceived stress captures only part of the experience of being busy.

Household Ethnographies

Microlevel studies complement macrolevel time allocation studies and allow researchers to address additional questions. Ethnographic interviewing permits researchers to ask questions that are meaningful to people about their lives and how they organize and process information about them, regardless of researchers' analytical categories. This insider perspective is arguably closer to the experiential dimension of busyness. Observational studies, especially when accompanied by informant commentaries, allow researchers to appreciate the subtle shifting between scripts, values, and meaning associated with activities that is an essential but tacit part of busyness. Talking through sequences of e-mails or text messages to family members, strangers, coworkers, and other acquaintances, for example, is accompanied by shifts between intimacy and distance, risk, and safety that are difficult to elicit in interviews, much less surveys.

Microlevel studies also allow researchers to study the moral order that underlies decisions about allocating time. Busyness implies knowledge about what people can, should, or must do. Activities are not simply performed, but they also entail different kinds of commitments to people and to how individuals define themselves. Individuals navigate days marked by activities and commitments, and they keep track of where and who they are; these, too, are time-consuming internal activities that accompany the behaviors of preparing meals, transporting children, and reading books or looking at screens. Above all, being busy is about what is not done and therefore not seen, as much as it is about what we do.

Graesch (2009) describes the procedures used by researchers conducting week-long studies of 32 working families in Los Angeles. The methodology included videography of parents and children in their homes, and an ethnoarchaeological approach to mapping and documenting family assets. Activities were captured using a scan sampling method in which behavior is sampled at regular predetermined times. Kitchens emerged as 'hubs of busyness', with clocks, calendars, telephones, and message-covered refrigerators providing the infrastructure for time management. These were homes where families had increased leisure, but also segmented, hectic schedules.

Darrah et al. (2007) followed 14 dual-career families throughout a sampling of days, journeying with them to work and school, as well as on numerous errands. Fieldwork revealed intelligence gathering, planning, prioritizing, and purchases of technology to manage or cope with busyness rather than a simple speeding up or acceleration of time. It provided details of how time, tasks, location, and meaning came together in specific situations, with the household as a setting for experimenting with ways to manage busyness. The older contrast between work and leisure was subordinated to new activities, including many created by deregulation and consumerism in the neoliberal state.

New Directions in Theory and Research

Research and theory germane to busyness continues to be generated in different disciplines, even without a comprehensive research agenda. The primary challenge of studying busyness remains that of integrating theory and findings from different disciplines and fields in order to provide a more holistic approach to how it is conceptualized and investigated. Time allocation studies provide continuity within the study of busyness, although the categorizations and data do not specifically address the concept of busyness. Several social science disciplines bring additional concepts, data, and questions to the field.

Distinguishing the mechanisms that lead to different facets of busyness is essential. Southerton and Tomlinson (2005), for example, discuss three elements of being harried that are consistent with busyness. They identify the volume of time to complete the tasks that people judge to be necessary so insufficient time to complete them results in expressions of being harried. Coordination becomes more difficult when daily lives occur in the context of casual, flexible, or ad hoc structures that necessitate individualized scheduling, often in real time. Consumption occurs within networks and 'omnivores' with wide-ranging interests have more networks that increase the cost of coordinating schedules and feelings of being rushed. Daily tasks, too, may be situated in temporal rhythms that become intensified, resulting in expressions of juggling and multitasking. Busyness is accordingly not unidimensional and it involves often tacit coordination activities that largely elude time allocation studies, with their summative approach to being busy.

Interest in busyness is partially motivated by concern that it has unintended, harmful consequences for both children and adults, such as stress or limited attention. The costs of busyness may include effects on learning and sociability, as well as productivity and job turnover. Explicating these costs and linking them to potential remedies is important to individuals, families, and workplaces, and also to public policy. Shifting focus from individual adjustments and adaptations to institutional responses, such as workplaces that are flexible in responding to the idiosyncratic commitments of workers is increasingly linked to worker recruitment, retention, and productivity.

Changing the constraints upon daily lives complements enhancing individuals in their ability to cope with busyness. One approach is to provide workplace, instead of worker flexibility through practices such as offering employees more control over scheduling work hours, places of work (e.g., telecommuting), and the number of hours worked, and even results-only work environments in which workers control work scheduling as long as productivity goals are met. Such flexible arrangements offer benefits as well as costs and they are not appropriate for all conditions. Although data regarding their impact is limited, they do provide opportunities to experiment with environmental conditions in order reduce the effects of busyness.

Although busyness sometimes seems to permeate society, its manifestations can be distributed. It may also provoke resistance such as through various slow movements that are the antithesis of efficiency and productivity. Globalized capitalism binds together many people around the world through networks of rapid communication, access to information, and consumption, but there is also a slow world in which the pace of life is relaxed through deliberate public policies. Miele (2008) describes CittàSlow, an international movement aimed at diffusing the philosophy of 'slow food' throughout urban design and planning to improve quality of life. Such movements as slow food and slow cities provide opportunities for people to create alternatives to social structures in which busyness is inevitable and difficult to avoid.

Finally, ITs, and personal mobile devices in particular, are deeply entangled with busyness. IT's material affordances allow the efficiency and mobility that provides people with the flexibility of working under conditions they choose, even if those efficiencies are often translated into taking on additional activities that increase aggregate busyness. But IT also provides products that are embedded in leisure practices that people enjoy, just as they add more to do each day. Researchers and designers continue to explore the potential of IT to enhance communication, collaboration, and coordination among multiple individuals, support nomadic work lives, and integrate our physical and digital worlds, but also to reduce busyness (Snyder et al., 2007). New technologies that allow communication through video chat or coordinating e-books for children to read with family members at a distance, and even calendar sharing applications, highlight the importance of staying connected and organized, and including extended family in those routines (Cao et al., 2010). Researchers are also focusing on potentially negative consequences of increased technology use that may affect busyness. Turkle (2011), for example, argues that IT use may not only influence time allocation by minimizing boredom and loneliness, but it may also reduce opportunities and incentives for self-reflection and building deeper connections with other people.

As theory and concepts about busyness have changed, so have methodological approaches. A first methodological issue is how to integrate data that describe behavior with those which capture the experiential component of busyness. Direct observations, surveys, and interviews provide data about behavior or people's recollections of it. There is, however, a gap between such description and evidence of busyness. Claims of being busy or not can be based on the analysis of time allocations by a community of researchers or by individuals who are describing their own lives. However, busyness is difficult to establish without talking to people about how they experience and categorize their daily activities. The private, internal work of busyness – anticipating, planning, adjusting, prioritizing, etc. – is only accessible through open-ended interviewing conducted in the flow of activities. Eliciting and integrating data about these two very different components of busyness is a central methodological challenge.

A second challenge is to integrate quantitative and qualitative perspectives on busyness. Considered quantitatively, busyness can be measured by an amount or level of activity calculated by summing minutes or hours or assessment of stress. Alternatively, busyness may be considered qualitatively by focusing on the types of activities – their nature and variety, duration, differentiation by scripts or rules, etc. – that create distinctions among activities that are critical to being busy. Here it is not the amount of activity that matters, but the

differentiation and complexity of activities, as well as their coordination and management.

Third, busyness can be examined at the level of individual lives or at that of a society that generate busyness. The former is the more familiar approach and it sensitizes researchers to how individuals make choices about their use of time. But it takes for granted those activities among which choice is being exercised. The latter approach draws attention to the social processes that entangle individuals in activities regardless of their choices. In effect, it treats as problematical the very activities that individuals choose among and it explicates the processes and structures that characterize a society and which produce individuals who are willing and able to embrace busyness.

A final challenge is to further develop international, cross-cultural approaches to busyness as a phenomenon that transcends national boundaries. Explanations that rely on national conditions can be complemented and strengthened by a comparative approach and international time allocation studies provide a foundation (Gershuny, 2000). However, surveys alone may be inadequate to provide the requisite data (Sullivan, 2008). The challenge is conceptual as well since busyness requires analysts to understand activities in detail, as well as how they are coordinated and experienced, a profound exercise in cross-cultural comparison.

Abstract

The American philosopher Judith Butler is one of the most influential scholars working in the field of contemporary critical theory. Best known for her contributions to gender theory and feminism, specifically for her account of gender as performative, her recent writings on international theory and global ethics, her critique of U.S. foreign policy in the wake of the wars in Iraq and Afghanistan, and her interest in the conflict in Israel–Palestine, have broadened her oeuvre and have made her work of interest to a wider public, beyond academia.

Biography

Questions of recognition, of who counts or matters, constitute a leitmotif of the writings of the American philosopher Judith Butler (1956–present). That her own work counts in the social sciences is beyond dispute, and no serious effort to survey the contemporary scene of social and political theory should omit her contribution. In fact, it is with considerable justification that Butler could be described as one of the most important contemporary critical theorists of the late twentieth and early twenty-first centuries. Her interventions into the feminist theory debates of the late 1980s and 1990s had a profound influence on the direction of contemporary feminist theorizing, and continue to shape the research agendas of many scholars working within this field. Terms such as performativity, vulnerability, and precariousness, introduced by Butler into wider contemporary critical discourse (see Butler, 1990, 2004a, 2009), firmly belong to the repertoire of social and political theorizing. Considered as one of the founders of queer theory, her unsettling of the category of gender and her deconstruction of gender's relationship to (biological) sex and desire remain hugely influential. Her more recent writings (2004a, 2009, 2012) on international theory and global ethics, her critique of U.S. foreign policy in the wake of the wars in Iraq and Afghanistan, and her interest in the conflict in Israel–Palestine have broadened her oeuvre beyond the boundaries of feminist scholarship and gender studies; they have also extended her public appeal beyond academia.

At present, Butler is Maxine Elliot Professor in the Department of Rhetoric and Comparative Literature and the Co-Director of the Program of Critical Theory at the University of California, Berkeley. She also holds the Hannah Arendt Chair of Philosophy at the European Graduate School in Switzerland, and she is Wun Tsun Tam Mellon Visiting Professor of the Humanities at Columbia University, New York. Previous academic appointments include two short periods at Wesleyan and John Hopkins universities. Butler is the recipient of many prizes and honors, including the Adorno Prize, awarded by the City of Frankfurt, Germany, for outstanding performances in the fields of philosophy, music, theater, and film. She is also a regular contributor to public events, such as those associated with the boycott, divestment, and sanctions (BDS) movement against Israeli policies in the occupied territories; she was a speaker at Occupy Wall Street and she served on the International Gay and Lesbian Human Rights Commission.

Butler's scholarly background lies in continental philosophy, and much of her writing is informed by the interplay between German and French ideas, specifically the works of Hegel and Foucault. We learn about her philosophical journey in *Subjects of Desire: Hegelian Reflections in Twentieth-Century France* (1987/1999), a book based on her doctoral thesis. In the preface to the book's second edition, Butler narrates the history of her scholarly training, including her graduate studies in German philosophy, specifically German idealism and, above all, the work of Hegel. Her interest in phenomenology led to a period of study in Heidelberg on a Fulbright scholarship, where she took classes with Hans-Georg Gadamer (1900–2002). Butler's focus on German philosophy swiftly broadened to encompass twentieth-century French thought, such as the writings of Simone de Beauvoir (1908–86), whose ideas underpin some of her early publications (see Butler, 1986, 1987). Hegel's philosophy continues to shape Butler's thinking to date, but following her completion of her doctorate at Yale University in 1984, she broadened the range of her philosophical interlocutors to include the ideas of French post-structuralism, in particular the works of Michel Foucault and Jacques Derrida. More recent texts engage with the writings of Theodor W. Adorno, Hannah Arendt, Walter Benjamin, Emmanuel Levinas, as well as Edward Said. Notwithstanding her initial reluctance to embrace psychoanalytic thought, Butler has also been profoundly influenced by the writings of Freud (see Butler, 1997a), and she pursues a critical engagement with the ideas of Jacques Lacan, Melanie Klein, and Jean Laplanche.

Butler's scholarly formation is closely intertwined with the context of her upbringing, which she articulates through the trope of trouble. To fully appreciate the development of her ideas, it is important to acknowledge two formative influences on her thinking: these are her upbringing as a Jew and her exposure to Judaic ideas as part of her education in her synagogue, and the lived experience of gender and sexuality in a heteronormative culture. In a recent interview (2011), Butler recounts how, as punishment for being troublesome, she was sent to classes with the rabbi. However, rather than experiencing these classes as penalty, she saw these lessons as an opportunity to engage with a set of ethical and philosophical questions that continue to occupy her thinking in the present: these are questions to do with ethical responsibility, the role of Jewishness, and wider questions of identity formation. The classes also introduced Butler to the works of Spinoza, whose conception of the *conatus*, interpreted by her as the desire to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61319-3

persist in one's being, has exercised a significant influence on her thought, articulated in her recent focus on the notion of livability (Butler, 2004b; see also Lloyd, 2008; Schippers, 2015). Equally significant, and perhaps better known, is her engagement with feminism and gender politics in the context of a heterosexist culture. As she tells her readers in her most famous book to date, *Gender Trouble: Feminism and the Subversion of Identity* (1990), the fate of two gender-troubled uncles and her own sexual identity formation have contributed to an early interest in questions of sexuality and its relation to gender. Central to the later development of this awareness is Butler's insistence on the power exerted by hegemonic regimes of gender regulation. It is this latter aspect that has informed her work on gender, identity, and feminism. These key themes weave themselves through Butler's oeuvre, beginning with early writings in philosophy, right up to her most recent texts on binationalism and global protest. Notwithstanding developments and additions in her thinking, her theoretical apparatus remains anchored in a set of key categories and approaches that stem from her early work on Hegel and Foucault, and the wider framework of continental philosophy.

Major Works

Desire, Power, and the Performativity of Gender

Given the wide range of influences on the development of Butler's ideas, it is impossible to align her work with one particular school of thought. However, three frameworks continue to inform her scholarly endeavors: post-structuralism, existential phenomenology, and psychoanalysis. These approaches also configure the persistent themes in Butler's work, which, although addressed in different contexts and at different stages of her academic career, evolve around questions of political subjectivity and conditions of alterity. As already mentioned, two thinkers feature prominently in the development of Butler's work: the French philosopher Michel Foucault and the towering figure in modern German philosophy, G.F.W. Hegel. While Foucault's conception of the subject as imbued with power has been hugely influential to Butler's writings, she borrows from Hegel her continued attention to questions of alterity and to recognition, specifically, how to engage with the other under conditions of unknowingness, and how to relate to the other upon whom the subject is dependent for its very physical survival. These themes feature prominently in Butler's recent writings on international theory (see Butler, 2004a, 2007, 2009), but they surface early on in her work. Of particular importance to the development of this early work on gender is her deployment of Hegel's concept of desire. In *Subjects of Desire: Hegelian Reflections in Twentieth-Century France* (1987/1999), Butler pursues the notion of desire in its encounter with the historicizing impetus and imperative articulated in the French reception of Hegel, specifically in the works of Alexandre Kojève, Jean Hyppolite, and Jean-Paul Sartre. Although Butler later belittles her book in the preface to the second edition as her juvenilia, *Subjects of Desire* flags up important themes that continue to inform her writings; these include her attention to conditions of alterity, recognition, and identity formation; they also encompass the historicizing impetus of power; and, central to the further development of her work, the acknowledgment of corporeality and affect, and their implication in power.

Subjects of Desire's concluding chapter, which covers the treatment of desire in the works of contemporary French theorists, including Lacan, Foucault, Derrida, and Kristeva, connects her early phenomenological studies with her later Foucauldian and Derridean writings, for which she is best known. A key figure in this transition is Simone de Beauvoir, whose relevance to Butler's thinking is twofold: first, de Beauvoir provides the link to Butler's work on gender and feminism; second, de Beauvoir's Hegelian readings, specifically the idea of becoming, prepare Butler's own reading of gender as performative (see below). The engagement with structuralist and post-structuralist influences, which surface toward the end of *Subjects of Desire*, together with her interest in existential phenomenology, shape the future direction of Butler's work, and they culminate in the publication of *Gender Trouble: Feminism and the Subversion of Identity* (1990). This book attends to three issues, considered as deeply problematic by Butler: (1) the representational claims of feminism; (2) the dominance of expressive theories of gender; and (3) structuralist accounts of sex, gender, and the body.

What underpins the discussion in *Gender Trouble* is Butler's criticism of feminism as a representational political project. In other words, she challenges those who claim that feminism can speak straightforwardly on behalf of women. Her ambition is both epistemological and normative: for her, political projects cannot and should not presume the homogeneity of the subjects they seek to represent. However, rather than abandoning feminism as a worthwhile political project, her assertion regarding the heterogeneity of the subjects of feminism, as well as the decentered nature of the category 'woman,' constitute the point of departure for her reformulation of feminism and gender. What drives the argument of *Gender Trouble* is Butler's discontent with expressive accounts of gender. She challenges in particular the sex-gender analogy, that is, the idea that gender, understood as the historical, social, or cultural representation of a biological body, relates in any direct way to the body. Instead of emanating from, or expressing, the 'truth' of a biological body, gender is said to be performative: it is a never-ending process of *doing* one's gender (rather than *being* a gender), conducted under constraint, restricted and policed by the norms of gender, and operating in what she terms a 'heterosexual matrix.' This matrix is a generative framework that produces heterosexual gender as normal, and that marginalizes nonnormative genders and sexual minorities. Further, the desire that is said to emanate from this sex-gender analogy is also deconstructed, opening up possibilities for different articulations between (sexed) body, gender identity, and sexual desire.

Gender Trouble's influence on the direction of feminist theory in the 1990s, and the controversy surrounding some of its key assertions, cannot be underestimated. Sympathetic readings have highlighted the value of Butler's ideas for a politics of difference that takes seriously the internal differentiation and heterogeneity of the subject of feminist politics (see Lloyd, 2007). Further, her Foucauldian-inspired analysis

of the body has contributed a great deal to scholarship that seeks to trace and illuminate the historical discursive constitution of sexed corporeality. Much of the criticism of Butler's ideas derives from her reference to drag, which she deploys as an allegory for practices of gender performativity. Drag, according to Butler, dramatizes and illustrates the illusion of expressive accounts of gender; that is, the claim that gender expresses the truth of the sexed body. Despite Butler's insistence that her use of drag served merely illustrative purposes, it was (mis-)read by some of her critics as a normative assertion of gender as a voluntaristic expression (see Benhabib, 1995; Nussbaum, 1999). Such a voluntarist account, according to her critics, constitutes a serious oversight of the deeply entrenched injustices that emerge from women's corporeal vulnerability and that limit the potential for women's agency. Butler's Foucauldian-inspired critical genealogy of the subject proved to be equally controversial, interpreted by some critics as an account of the death of the subject and a denial of female agency (see Benhabib, 1995). A more challenging debate ensued around Butler's account of the body and the status of its materiality, or 'fleshiness.' These questions are taken up in *Bodies That Matter: On the Discursive Limits of* "Sex" (1993), where Butler revisits and clarifies some of her ideas presented in *Gender Trouble*; whereas *Gender Trouble* maps and critiques the conceptual terrain on which feminist theorizing of gender has operated, *Bodies That Matter* attends to the historicity of the body's materiality, and of the body's implication in (heteronormative) discourses of power.

Toward the end of the 1990s and into the 2000s, Butler's writings open up new areas of critical inquiry, focusing on international theory and (global) ethics (see Butler, 1996, 2004a, 2005, 2009). However, she keeps returning to gender theory and feminism, and to questions of sexuality and desire. These themes are brought together in *Antigone's Claim: Kinship between Life and Death* (2000a). Profitably read as a treatise on the gendered nature of speech, and as a development of Butler's previous work on speech act theory and the performativity of language (see 1997b), *Antigone's Claim* also constitutes a significant intervention into public debates on marriage equality. The book is underpinned by a philosophically informed discussion on the vagaries of kinship structures in the context of a heterosexist culture, and it deconstructs the contours of these heterosexual kinship arrangements. In *Undoing Gender* (2004b), a collection of essays on what she terms the New Gender Politics, an alliance of feminist, gay, lesbian, and trans and intersex movements focused on the pursuit of progressive sexual politics, Butler tracks the radical challenge, emanating from trans and intersex movements to the categories of gender and feminist theory, specifically to the idea of womanhood, of binary conceptions of gender, and, yet again, of feminism's representational claims.

Power and the Psyche

The trans and intersex movements also expose the deeply entrenched violence at work in the operation of gender norms, and in the policing, regulation, and forced correction of bodies. To map such deep-rooted subjection to norms, Butler draws on the ideas of Sigmund Freud, which she reads through the lens of Hegelian and Foucauldian philosophy. In *Gender Trouble*, she presents a critical reading of Freud's narrative of the acquisition gender identity that challenges its alleged heterosexist presuppositions. She returns to Freud's ideas in *The Psychic Life of Power: Theories in Subjection* (1997a), where she ponders the persistent attachment of subjects to their own subjection. Supplementing her reading of Freud with insights from Hegelian and Foucauldian philosophy, she builds on Freud's concept of melancholia, arguing that the melancholic attachment to a same-sex love object becomes incorporated as the barred prohibition of homosexuality. This internalized prohibition of homosexuality contributes to the development of (heterosexual) conscience, and it explains the often violent abjection of homosexual identification.

This development in Butler's theory of gender is significant because it puts to rest any assertions relating to an alleged voluntarism in her theory of the subject. Equally significant to Butler's discussion in *The Psychic Life of Power* is her continued reading of Hegel and Foucault. Of key importance to Butler's Hegel reception is the *Phenomenology of Spirit* (1977), in particular Hegel's narrative of the master–slave dialectic and the ensuing struggle for recognition. *The Psychic Life of Power* develops this reading of the *Phenomenology* by drawing on the Foucauldian notion of *assujetissement*. Thus, reading Hegel through Foucault, Butler articulates a concept of modern subjectivity as paradoxical. Becoming a subject entails subjection to norms and to an other, which the subject experiences as deeply agonizing. Yet at the same time, subjection brings the subject into existence as intelligible and recognizable, enabling being and persistence (hence the link to Spinoza). Developing this insight, Butler concludes that the subject is passionately attached to its own subjection: for Butler, there is no subject without subjection. The idea of a passionate attachment to subjection is also instrumental in the development of her thought after 9/11 and her turn to questions of ethics.

International Theory, Universality, and the Turn to Ethics

One of the more heavily debated topics in the recent Butler scholarship relates to her so-called turn to ethics (see Dean, 2008; Lloyd, 2008; Rushing, 2010; Schippers, 2015). This aspect of Butler's work has puzzled many of her readers because it seems to run counter to a concern, expressed in her earlier work, that the alleged universalist and formalist assumptions of ethics may be at odds with the kind of Foucauldian investigations to which she remains committed; ethics, she worried, may replace or displace a concern with power and politics. However, building on her reformulation of the critique of universalism (see 1996, 1997b, 2000b), her recent work espouses the importance of ethics and its relevance for understanding politics in the post-9/11 era. This interest in the political fallout of 9/11 should be considered alongside her foregrounding of a new set of political concepts, such as her pursuit of the question of responsibility, which she articulates in relation to post-9/11 politics, and in her discussion of Zionism and the conflict in Israel–Palestine. It also informs her ongoing interest in conceptions of the subject: although Butler remains attuned

to subjectivity's gendered dimension, she has added to her repertoire by considering subjecthood in the context of global interdependence, and by pondering its ethnic and racial framing under conditions of war.

The source for this interest can yet again be traced back to her early work on Hegel and existential phenomenology; there, Butler articulates a narrative of the subject as relational and fundamentally dependent upon others. Its political context lies in the events surrounding the attacks on September 11, and the ensuing military invasions of Afghanistan and Iraq. It is in the encounter with these political events that Butler reformulates her questions and interests, and reworks her conceptual apparatus, which lead her to foreground the notions of precariousness and precarity, vulnerability, violence and grievability, and livability. In her two most significant works of the last decade, *Precarious Life: The Powers of Mourning and Violence* (2004a) and *Frames of War: When Is Life Grievable?* (2009), Butler challenges those assertions which insist on the unconditional sovereignty of the state and its right to engage unilaterally in acts of war. Against such assertions of sovereignty, she champions instead an account of global interdependence, which would reconfigure dominant patterns of recognizability, and which could sustain the livability of populations across diverse ethnic and racial frames. Building on her critical reading of the ideas of Emmanuel Levinas, Butler suggests that human life is subject to a fundamental vulnerability and precariousness, dependent upon the care provided by others. Such care, however, is distributed unequally, leaving some populations more exposed to violence than others.

Jewish Philosophy and the Politics of Cohabitation

Much of Butler's criticism of U.S. foreign policy since 9/11 turns on her effort to articulate a critique of violence that acknowledges violence's paradoxical role as simultaneously destructive and constitutive. This critique of violence, conducted in the context of the war on terror, the military invasions of Iraq and Afghanistan, and the treatment of detainees at Abu Ghraib and Guantánamo Bay, informs another area of scholarly inquiry and public engagement: this is Butler's intervention into the conflict in Israel–Palestine. Two issues occupy her writings in this area: first, she challenges those positions that frame criticism of Israel as inherently anti-Semitic (see Butler, 2004a, 2012). Developing her discussion of hate speech (see Butler, 1997b), she aims to articulate a specifically Jewish position from which to criticize Israeli state violence. Such a position would not only challenge the claim that criticism of Israel is, by definition, anti-Semitic; it would also put forward a distinctively Jewish critique of violence from which to judge the violent actions of the (Israeli) state.

A further facet of Butler's engagement with Jewishness pertains to practices of state formation and citizenship in the context of heterogeneous populations. In brief, she seeks to formulate conceptions of a polity beyond nationalism that would facilitate heterogeneous populations, such as those inhabiting the territory of Israel–Palestine, and to construct forms of citizenship that accommodate plurality. These themes are outlined in one of Butler's most recent books, *Parting Ways: Jewishness and the Critique of Zionism* (2012). Drawing on work by Hannah Arendt, Edward Said, and Emmanuel Levinas, Butler thinks through prospects for cohabitation in multiple inhabited spaces, across boundaries, and within contested political spaces. Such considerations of citizenship also inform her reflections on the fate of illegal migrants and their precarious status. This latter point features in *Who Sings the Nation-State? Language, Politics, Belonging* (2007), a conversation with Gayatri Spivak on the role of the nation-state under conditions of migration, multiculturalism, and global interdependence. Both considerations, on conditions of contested state borders and on migration, are underpinned by her critique of the nation-state, which Butler, following the work of Arendt, regards as structurally prone to producing and expelling minorities. As yet, this aspect of Butler's writings is not as developed as her ideas on gender and feminism, or her discussion of vulnerability and precariousness, but it opens up a new field which explores the prospects for citizenship under conditions of heterogeneity and plurality, and which connects her recent writings with current debates in international theory and in political studies and sociology more widely.

Impact

It would be imprudent to identify the lasting impact of a living writer who produces scholarly output at the staggering rate that Butler does. Judging by Butler's most recent work, on Jewishness, Zionism, and the critique of Israel (2012), and on the politics of the performative in the era of global protest (2013), it is fair to claim that her writings continue to bear out her attentiveness to significant developments in the politics of the left. Of particular interest to her readers has been Butler's explicit connection between pressing political problems and the sophisticated philosophical considerations that underpin her analyses. Her pronouncements on global ethics, her advocacy of binationalism, and her criticism of state violence, as well as her work on Jewishness, are underpinned by her articulation of a relational account of the subject and the assertion of the subject as vulnerable, and by her reflections on what she terms a politics of dispossession, out of which ethical obligations toward (potentially distant) others arise. Her writings on ethics and violence have already made a substantial impact on the Butler scholarship (Chambers and Carver, 2008; Lloyd, 2008; Rushing, 2010; Schippers, 2015.). But while her recent work has received some attention in the field of international theory (Schippers, 2014), it has, as yet, not attained the same level of attention as her earlier work on gender. Given the relative novelty of her recent writings on Jewishness and binationalism, and her criticism of Israel, it is too early to establish their significance beyond the immediate Butler scholarship.

To give a fair assessment of Butler's wider impact, it is important to acknowledge her influence beyond the boundaries of the academy. Butler is a sought-after speaker at scholarly and nonscholarly events alike, and her recent works on international politics, such as her criticism of U.S. foreign policy and her support for the BDS campaign, have

opened her work and ideas to new audiences. The importance accorded to interventions into public policy is also reflected in the outlets of Butler's contributions: she is a regular interviewee for scholarly and nonscholarly publications, and many of her interviews and speeches can now be accessed online (many of these are available on YouTube). However, Butler's public statements, specifically in relation to Israel and her support for the BDS movement, have also left their mark and led to a series of hostile encounters and indeed threats.

Undoubtedly, it is in the fields of gender studies, feminism, and queer theory that her impact is most widely felt. Her writings have led to numerous and still growing publications, both critical and sympathetic. Her deployment of the trope of 'trouble,' which opens her discussion in *Gender Trouble*, has inspired those readers who, like Butler, aim to unsettle hegemonic conceptions of gender, gender relations, and the role of feminism. Despite the, at times stinging, criticism of Butler, notoriously described by Martha C. Nussbaum as 'Professor of Parody' (1999), it is with the notion of performativity that she has made a lasting impact on the theorizing of gender for more than two decades. Further, Butler's work on the new gender politics (2004b) has broadened the appeal of her ideas beyond the initial concern for the alleged heterosexist presumptions of feminist theory. This focus on her enormous contribution to gender theory should not cloud her equally significant role in the development of contemporary critical thought beyond gender. While her scholarly contributions alone, specifically her articulation of a relational conception of the subject, her theory of performativity, or her reworking of universalism are of considerable merit, they gain additional force through the way that they relate to the political and social problems of the early twenty-first century. One can only hope that Butler will continue to stimulate her readers with more work.

Abstract

The Cambridge School of Intellectual History is most associated with the work of Quentin Skinner and John Pocock, but encompasses the work of a number of scholars of political thought and political philosophy who have had connections with the University of Cambridge from the 1950s to the present. Members of the Cambridge School, who now teach at institutions of higher education across the globe, share a commitment to the historical study of texts, and reject approaches characterized by presentism and teleology (labeled prolepsis). They also reject canons of dominant authors and histories of philosophy that evaluate past ideas. Members of the Cambridge School have accordingly been in the vanguard of a historical turn in the study of past politics and ideas more generally, alongside the similarly historically minded approach, albeit distinctive methodologically, of Begriffsgeschichte or Conceptual History pioneered by Otto Brunner, Werner Conze, and Reinhart Koselleck. Beyond a belief in the need to establish a context for the understanding of historical texts, and distaste for grand or theory-inspired narratives, the members of the Cambridge School have conflicting views of the origins and nature of modern political thought. This is illustrated through a comparison of the work of Skinner and Pocock.

Introduction

The philosopher R.G. Collingwood, in his posthumously published *The Idea of History* (1946) made the argument that the past could not be understood by reference only to what he called the 'outside' of events, the facts about bodies and their movements. It was additionally necessary to describe the 'inside' of actions, or the relationship between an act and what was later termed its ideological context. The famous example Collingwood gave was of Julius Caesar's assassination. The murder could be described by reference to the assault on Caesar near Theatre of Pompey on the Ides of March, the descent of the knives into his flesh, and the resulting flow of blood. But this did not explain why it happened. Understanding Caesar's death entailed knowledge of Caesar's mind and those of his enemies Gaius Cassius Longinus and Marcus Junius Brutus. Caesar was killed because of his recent ascent to the position of long-standing dictator (dictator perpetuo). He was seen as a tyrant and a proponent of political ideas that clashed with the assassins' perspective on the nature of the Roman Republic and of constitutional law. In short, the reconstruction of ideas expressed by historical actors was necessary to any act of historical understanding.

Only 3 years after the appearance of Collingwood's book Peter Laslett published an edition of the political writings of Robert Filmer, the seventeenth-century advocate of the divine right of monarchs. He spent the following years working on something more monumental; a critical edition of John Locke's *Two Treatises of Government*, which appeared in 1960. Laslett was seeking to date the authorship of texts, and used evidence drawn from contemporary correspondence and commentaries to reveal that Filmer's *Patriarcha* had been composed prior to his other writings, but was only published posthumously between 1679 and 1680. More surprisingly still, Locke's classic work of political thought, rather than being a defense of the 'Glorious Revolution,' as it had traditionally been described, having appeared in print from 1690, was shown to have been written around 1681, at a time when Whigs of Locke's stamp were contemplating violence against the Stuart court. Laslett's editions raised questions for historians concerning the relationship between an author's intentions in writing a text and the intentions behind its publication, causing in the process a wholesale reevaluation of late seventeenth-century political thought. Collingwood's demand that historians think about the ideas of historical actors in their own time, and Laslett's that an author's intentions could be reconstructed from textual evidence, led to the establishment of the Cambridge School.

In treating Caesar as a historical individual whose ideas were accessible through his writings, Collingwood was arguing against approaches to history that emphasized the special qualities of great men. In arguing that Locke was not the author whose writings had justified the Glorious Revolution of 1688–89, but rather an activist in politics whose ideas for rebellion had come to nothing a decade earlier, Laslett was directly questioning traditional Whig historiography, in which liberty was readily identifiable, acquired and defended in England, from the time of the Magna Carta, an approach associated with Henry Hallam's *Constitutional History of England* (1827) or Thomas Babbington Macaulay's *The History of England from the Accession of James II* (1848). Whig approaches assuming historical progress and linear development were

lauded by readers as justifications of the glorious national present, and as such sustained the role of the historian as a public intellectual and sometimes as a public moralist. The point the critics of the Whigs were making was that this was all well and good, but the result was not history. True historians had to be skeptical of grand narratives, of presumed straightforward connections between the present and the past, and of teleological accounts founded on the assumption of gradual improvement. Herbert Butterfield made all of these arguments in *The Whig Interpretation of History* (1931), attacking the presumed causal linkage between progress, Protestantism and liberty that he saw as underlying nineteenth-century Whig historiography. The following generation of historians in Cambridge became skeptics, seeking to challenge what they held to be the formulaic and inaccurate philosophies of history of the overconfident Victorians and their successors.

The Cambridge Method

What exactly an anti-Whig historiography would look like remained uncertain, especially because Butterfield himself was doubtful that it could be written in practice, as evinced by his own *The Englishman and His History* (1944). But the following generation of historians took the challenge seriously. In the 1950s and 1960s, substantive reinterpretations of early modern intellectual history were authored by Felix Gilbert, Caroline Robbins, Hans Baron, John Pocock, and Bernard Bailyn. The work of these historians emphasized discontinuity, unintended consequences, tragic failures, and lost traditions of political argument; investigated 'minor' figures and used them to illuminate neglected elements of the thought of figures traditionally deemed canonical; and opposed overarching narratives or those inspired by philosophers' perspectives upon history, and especially that of Karl Marx. Attacks on the methods employed in writing such Whig histories, the North American equivalent of which was the notion of evolving 'unit ideas' associated with the work of A.O. Lovejoy, were written by John Pocock ('The History of Political Thought: A Methodological Enquiry'), John Dunn ('The Identity of the History of Ideas'), and Quentin Skinner ('Meaning and Understanding in the History of Ideas') between 1962 and 1969, all then associated with the University of Cambridge. They have come to be seen as classic statements about the practice of intellectual history in the area of political thought. Skinner's 'Meaning and Understanding' proved especially influential, and has been described as the manifesto of the 'Cambridge School,' in part because it identified opponents most clearly, and condemned with particular verve descriptions of classic texts as the 'sole object of inquiry,' and as contributing to a 'dateless wisdom.' Skinner attacked the presumed connections between canonical authors by reference to presumed historical continuities and political philosophies. He argued that historians of political thought were attributing to past authors concepts that could not have been available to them (the sin of anachronism) and sought in the work of historic authors anticipations of arguments, which could not actually be found in the texts (the sin of prolepsis). Skinner demanded that the arguments of texts be treated as acts performed in history. Such arguments needed to be related to the discourses of the time, identified as the context, being related or opposed to arguments articulated by people who were living at the time of the author and whose work would have been known to the author. Skinner said that the goal of the historian was to reveal what the author of a particular text 'was doing,' encompassing what the author had intended to do and had succeeded in doing as interpreted by the responses of other authors. One of Skinner's most fascinating points was that the language or discourse in which an author was working, meaning the set of assumptions that he was adopting and employing in the articulation of his arguments, set limits to the argument itself. Authors could innovate and alter existing languages, but the point was to search for exactly this because existing languages were employed in articulating what was happening in the ideological and material present.

In each of their essays, Pocock, Dunn, and Skinner proposed that texts be treated as products of specific historical contexts. In working out the meaning of the texts, Dunn and Skinner identified the intentions of an author as the principal guide to the nature of the text, although neither unproblematic as an intellectual objective, nor sufficient in terms of understanding an author's work. The three authors opposed approaches founded on the presumption of fixed concepts of historical analysis, of meta-theoretical assumptions about human nature, and of opaque or a historical theoretical vocabularies. Within the historical fraternity, one goal of the attempt to analyze utterances in political texts as 'speech acts' was to liken them to the 'acts' analyzed by fellow historians, thereby countering prevalent Namierite opposition in Anglophone circles to the study of ideas (Lewis Namier had called intellectual history 'flapdoodle' in his England in the Age of the American Revolution published in 1930). This aspect of the enterprise has been the most obviously successful, as a generation of scholars has confidently described themselves as intellectual historians, formed professional associations, and acquired academic positions in this field. At the same time the methodology of the Cambridge School has been attacked by Straussians, Marxists, empirical political scientists (behaviorists), and post-structuralists. Critics have questioned the capacity of any scholar to identify an author's intentions, or to get 'inside the mind' or a historical actor, and at the same time have stated that a method that limits itself to the recovery of past ideas, and rejects any evaluation of such ideas as anachronistic, amounts to the worst kind of antiquarianism.

Pocock's and Skinner's Historical Writing

Among the major questions for historians in the 1970s was the extent to which use of the 'Cambridge' method would alter contemporary perspectives upon the history of political thought? Amidst a range of revisionist interpretations, Pocock's *The Machiavellian Moment* (1975) and Skinner's *Foundations of Modern Political Thought* (1978) have been seen to be seminal, and more especially interesting because of their earlier methodological essays. Pocock's *The Machiavellian Moment* followed his earlier *The Ancient Constitution and the Feudal Law* (1957) in leading historians to broaden their definition of early modern political theory, which was shown to encompass civil law, theology, and political economy, by contrast with many narrower twentieth-century conceptions, which had inspired

altogether different readings of history. *The Machiavellian Moment* dealt with changing concepts of time from Aristotle to the American Revolution and the 'Machiavellian' reflection upon the foundation and crisis of republican states. Skinner's *Foundations* commenced with a volume on Renaissance political theories and a second volume on 'The Age of the Reformation,' describing the gradual identification of the state with an artificial person standing above the unruly elements of political society, being a potential solution to endemic religious conflict. Skinner's work ended with scrutiny of the resistance theories of the early seventeenth century, by which time modern politics were in his view discernable. Each work generated a great deal of scholarly comment, much of which has linked them together as the most important studies to date of early modern political thought in Europe and the Atlantic World. They deserve particular attention as test cases of whether the practice followed the method, and successfully changed the way intellectual historians worked if they adopted the 'Cambridge' standard.

Skinner and Pocock agreed on the importance in early modern history of the articulation of a view of human flourishing developed in the Italian city republics from the thirteenth century onwards, in which a life lived in an independent republic was praised as natural to man, and in which civic activity to sustain this state was described as being the highest secular aspiration. They agreed on little else. Neither Pocock nor Skinner had ever anticipated agreement about intellectual inquiry. But the extent of the disagreement was perhaps surprising, given the extent to which each shared, broadly, the same approach to the past in terms of method. Many have seen such disagreement as indicating that the Cambridge method would not lead to more obviously improved understanding of the past, and have questioned whether the Cambridge School exists, beyond a rejection of teleology and prolepsis.

Pocock's history of civic humanism extended chronologically and geographically, describing James Harrington's adaptation in the mid-seventeenth century of Machiavelli's perspective on the history of Rome, according to which the practice of arms and inheritable landed property were the precondition for the enjoyment of liberty and the exercise of civic virtue. Pocock went on to detail the controversy over this perspective in the eighteenth century, in the very different context of ideas about liberty and autonomy that accompanied the end of the wars of religion and the rise of large and competing commercial monarchies in Europe. Maintaining these new forms of state required the development of standing armies and public credit; these were defended by association with modern forms of politeness, and praised by such men as Daniel Defoe alongside consumption and financial independence, in societies organized in accordance with the division of labor. 'Neo-Harringtonians,' as Pocock termed them, such as Andrew Fletcher, favored ancient virtue, protected and sustained by militias and an elite of landowners, whose interest in the state ensured their political wisdom and the moderation of their laws. The neo-Harringtonians despised modern politeness, believing it to entail the corrosion of masculinity, the growth of forms of corruption accompanying the rise of parties and the specialist politician, and far greater uncertainty in civil society and in politics, exemplified by the reliance of the state upon the expertise of the stockjobber.

The clash between 'ancient' and 'modern' ideas about liberty has been characterized by Pocock as a debate in which the ancients saw liberty as a "direct act of the personality…the liberty of the hedgehog who knows himself but may know nothing else" and in which the moderns supposed liberty to entail the mediation of the personality, "through all the multifarious activities which may relate humans to one another in society…the liberty of the fox, who knows so many things that he may have no self left to know." In the Atlantic world, the controversy was characterized by concerns about the likely stability of real and of moveable property, and was in turn complicated both by the domestically uncertain identity of composite states comprised of different 'nations,' and by discussions in Protestant and Catholic states of the likely consequences of commercial society for religious belief, some of which questioned the compatibility of different forms of Christian worship with a polity competing for survival by commerce and by war. This state of affairs in turn generated an influential literature of jeremiad, which was particularly marked in the writings of historians, politicians, and philosophers in the late eighteenth century. Pocock has always contended that such issues remain identifiable in the political cultures of modern states, and particularly the North American Republic, and this has been one of the reasons for the controversial reception of his work within and beyond the academy.

In the *Foundations*, Skinner narrated a distinctive story, which challenged Pocock's account by emphasizing the differences between the Greek and the Roman political heritage, arguing specifically that Pocock had overestimated the importance of Aristotle's *Politics* as a source of Renaissance understanding of what it meant for citizens to live as equally sovereign agents in a law-governed republic. For Skinner, civic humanism was more heavily indebted to Cicero, who had extolled the life of civic virtue and republican citizenship that was possible under a free government. From Pocock's perspective, the fundamental difference between his view of civic humanism and Skinner's lies in the importance of justice as a political value. While Cicero encouraged the enjoyment of all the goods of human society and their just distribution, entailing the development of a moral code capable of defining and sustaining the life fully lived, Machiavelli was less concerned with justice and morals than with *virtù*, and placed personal autonomy and public participation at the center of his political philosophy. For Pocock, historical Ciceronianism was more a moral philosophy than a doctrine for political action, and it was Machiavelli's distinctive vision, which defined republican thought and the practice in Europe's small states, enjoying another history when it was adapted to the circumstances of Europe's larger monarchies and their colonial empires. The 'Afterword' to *The Machiavellian Moment* is revealing of Pocock's response to Skinner's criticism. It states that Skinner's approach should be placed within the history of jurisprudence, rather than being directly related to the republicanism of Machiavelli. Pocock has argued that Skinner's study of the emergence of the state should been seen as a contribution to 'the ideology of liberal empire,' founded on acceptance of the transformation of a republic into an empire, because the Ciceronian virtues Skinner described were capable of being realized under popular rule or the rule of a prince, such as

Augustus, Trajan, or Justinian, or indeed the 'sacred' monarch described by Eusebius, because of the existence of law. Pocock has criticized the notion that civic humanist ideas that paralleled the Florentine condemnation of tyrannical princes could be found in Otto of Freising's writings in the twelfth century. Pocock's argument is that none of Skinner's cast take seriously the idea of decline and fall, which became so powerful in European thought, questioning whether liberty depended upon law, and holding that virtues could easily be lost and states distempered and destroyed in consequence. In other words, Skinner has neglected to place texts in a context that is sufficiently broad. This criticism fits with Pocock's own description of the intellectual journey he has undertaken since *The Machiavellian Moment*. Pocock now states that his own notion of the politics employed in 1975 was insufficiently encompassing, especially of the theological ideas that played such a prominent role in seventeenth- and eighteenth-century life. A more theologically embedded perspective on politics has characterized his subsequent historical writing, and most directly that concerning Edward Gibbon's *Decline and Fall*.

The Origins of Modern Political Thought

Skinner's work since the *Foundations* has included major reinterpretation of Thomas Hobbes' perspective upon rhetoric and engagement with Aristotle, which for many exemplifies the Cambridge method. At the same time Skinner has retained an emphasis on the impersonal character of the modern state and an interest in the origins of modern ideas about liberty. It is in this area that his work has been most controversial. In *Liberty before Liberalism* (1998) and in a number of essays, Skinner has taken steps to refute the accusation of antiquarianism, by underscoring the continuing importance of a neglected tradition of political argument, evident after the regicide of 1649, when John Milton, Marchamont Nedham, and others were commissioned to defend the new state. Milton and Nedham were convinced that the actions of a political body had to be determined by the will of its members. They advocated representation rather than democracy, defining democracy as a system in which the people acted as their own government. Representation, by contrast, was one means of promoting government by the most virtuous and most wise, although Milton and Nedham recognized that it would also be necessary to have laws that encouraged *virtù* in the people, raising the possibility of laws to force citizens to be free. Arguing against the exercise of prerogative power by governments, Milton and Nedham held that the existence of such executive powers rendered subjects or citizens unfree, because of the threat to life and to property inherent in the existence of such powers. As such, they countered Hobbes's definition of a free man as someone 'not hindered to do what he has a will to' by praising civil liberty and political action with reference to Sallust, Seneca, and Tacitus. In consequence, Skinner has termed the doctrine of Milton and Nedham "the neo-Roman theory of free states and free citizens."

The essence of the neo-Roman theory was nicely captured in Harrington's response to Hobbes' famous claim that the liberty proclaimed on the turrets of the city of Lucca was illusory, because the extent of the citizens' freedom within the law was no greater than that enjoyed under the Sultan. Harrington stated that "even the greatest bashaw in Constantinople is merely a tenant of his head," enabling Skinner to conclude that an obsession with certain civil rights to be asserted against governmental power characterized by the thought of the neo-Romans, and constituted a significant classical legacy to modern politics. That someone is not free unless they are free from direct coercion, or indeed from the threat or likelihood of coercion, is a perspective that Skinner wants to reassert today, especially in cases where we may presume ourselves to be free, but where we are not because of the coercive potential of state action, or that of other corporate bodies.

Skinner's restated "foundations of modern political thought," with the lost tradition of Milton and Nedham added, have been criticized on numerous grounds. The concern with a fixed 'concept' of liberty defining a developing historical school of thought identical with Skinner's personal political philosophy, and deemed to be of direct relevance to modern problems in politics, has been called whiggish, and has been likened to the approaches founded on prolepsis that Skinner attacked in 'Meaning and Understanding.' The fact that none of Skinner's cast called themselves neo-Romans and advocates of a particular approach to liberty, or identified themselves as a separate group with the other authors listed as neo-Romans or opponents of slavery, has led to the accusation that Skinner's categories are ahistorical, or at best misleading, because they were not used by the historical actors concerned. Despite being the person who has done the most in recent years to bring philosophers and intellectual historians into dialogue, Skinner has been accused of being too much of a historian and too much of a philosopher by members of each tribe. His definition of politics as comprising precise but narrow concepts, explicable by means of a critique of Isaiah Berlin's discussion of liberty in the mid-twentieth century, has also been described as too blunt an instrument of early modern historical analysis, in part because of Pocock's success, and that of Jonathan Clark, Colin Kidd and others, in studying early modern politics together with theology and political economy. Skinner's claim that the neo-Romans' idea of 'civil liberty' was 'strictly political' is odd in that it implies that the neo-Romans were uninterested in the nature of the Christian polity, and in the forms of international competition considered vital to maintain security.

Some of these criticisms can be seen to have missed their target once it is accepted that Skinner's main aim has been to make sense of a complicated controversy over the meaning of liberty in seventeenth-century England, while valuably reminding his audience that liberalism is itself a historical construct. If the rise of the impersonal state remains central to Skinner's interpretation of modern political thought, a genuine question is the nature of the neo-Roman response, from the late seventeenth century, to the great change in attitudes that accompanied the rise of commercial monarchies that were able to use public credit to fight wars. This difficulty was identified sometime ago by John Dunn, Skinner's sometime Cambridge colleague, who has argued that Skinner's definition of the political is too narrow, and largely irrelevant to the modern world because it does not take seriously the economic limits to modern politics, in the form of debts and their consequences for national security, which have dominated political discussion since the early eighteenth century. In Dunn's view, the more accurate foundations of modern political thought have been delineated by Istvan

Hont in his *Jealousy of Trade* (2006), describing the battle about the relationship between the political control of the economy and the economic control of politics since David Hume sought to refute Bernard Mandeville's view of commercial society. Hont's work has inspired an international turn in intellectual historical research, which is leading to the reinterpretation of political thought from the seventeenth century to the present.

What all of this means is that while the term 'Cambridge School' is increasingly seen to be a misnomer, because those associated with it disagree about almost every aspect of the history of political thought, the Cambridge historians have at the same time produced a remarkable body of work that has contributed to the success of intellectual history in disciplines across the humanities. Facile assumptions of intellectual progress have been abandoned, and the use of modern categories in charting alien intellectual landscapes is increasingly questioned.

Abstract

Political campaigns can be viewed at a micro- or a macro-level. At the micro-level, campaigning involves an individual candidate attempting to win political office. At the macro-level, political parties seek to gain seats in government for their partisans and ultimately to gain power or at least to share power in the relevant governmental arena. At each level the same steps in the process must be followed – decisions must be made about candidacies, organizations must be built, messages must be refined, strategies must be set, and the public must be convinced to support those waging a particular campaign. Only certain aspects of political campaigns are viewed by the public. Most frequently, the actions taken away from public view are more determinative of success or failure.

At the microlevel, political campaigning involves an individual candidate attempting to win political office. At the macrolevel, political parties seek to gain seats in government for their partisans and ultimately to gain power or at least to share power in the relevant governmental arena. At each level decisions must be made about candidacies, organizations must be built, messages must be refined, strategies must be set, and the public must be convinced to support those waging a particular campaign. Only certain aspects of political campaigns are viewed by the public. Frequently, the actions taken away from public view are more determinative of success and failure.

The Choice of Candidates

Decisions about who will run for office involve decisions by potential candidates as to whether or not they will run and decisions by political parties, acting under a variety of rules, concerning who their candidates will be.

The Decision to Run

Individuals who run for political office must exhibit political ambition beyond the desire to simply serve their community. Campaigning for and serving in political office involves personal costs and public exposure that deter many from seeking office. However, even those ambitious for elective office must make decisions about what offices to seek and when to seek those offices (Jacobson and Kernell, 1981). These decisions are based on a complex, often-implicit cost-benefit analysis. Potential candidates weigh the costs and benefits of both winning and losing. Their decision calculus can be summarized:

$$p_r = p_w(B_w - C_w) + p_l(B_l - C_l)$$

where p_r = probability of running; p_w = probability of winning; p_l = probability of losing; B_w = benefit of winning; C_w = cost of winning; B_l = benefit of losing; C_l = cost of losing.

The difficulty that potential candidates face in making these decisions relates to the uncertainty regarding virtually all of the relevant variables (Maisel, 1986; Kazee, 1994). Generally the rather obvious benefits far outweigh the costs of winning for those with the requisite political ambition; but costs must be weighed – loss of privacy, loss of time with family, frequently loss of income. Similarly, the evident costs of losing are almost always greater than the benefits; but some benefits do accrue to losers – making a name for oneself, building up good will with party officials. Beyond these broad generalizations, little is known about how specific candidates make individual decisions given the dazzling array of difficult-to-estimate variables (Maisel and Stone, 1997).

Parties' Choices of Candidates

The ways in which political parties choose their candidates for office varies significantly from political system to political system and from party to party. The key variable in this aspect of the process relates to the extent to which party organization controls places on the ballot contrasted with voters acting independently. In the former, the process is often described as candidate recruitment, in the latter, candidate emergence.

At one extreme are those systems in which political parties slate their candidates for office, ranking candidates or placing them in safe constituencies. Most parties operating in electoral systems with proportional representation follow this procedure. It is also followed in systems with strong party systems, in which citizens vote more for parties than they do for individual candidates. Many European systems fit this description (Hix and Lord, 1997).

At the other extreme are systems, of which the United States is prototypical, in which voters choose party candidates in primary elections. The shape of the electorate in primary elections varies considerably from polity to polity. In theory, primary elections are open only to members of one political party or another, but in actual practice how membership is defined varies according to local rules and can be quite restrictive or totally open. In either case, voters in the primary elections determine the party nominee, even if that nominee would not have been the choice of party officials (Maisel, 1999).

Many systems are hybrids, with party officials and the voters sharing power. The US presidential nominating system stands

as perhaps the most complex means of choosing party candidates. Delegates elected to national party conventions make the actual nominations. Some delegates are selected because of their positions within the party or as elected officials with party affiliations; others are chosen at party meetings (or caucuses) held in local communities; still others are chosen by the voters in primary elections, based on lists of delegate candidates approved by the presidential campaigns they seek to support (Polsby and Wildavsky, 2000; Wayne, 2000).

The Campaign Organization

In polities with strong party systems, campaign organizations tend to be party-centered. In these cases, the voters cast their ballots for candidates as representatives of a party. The party defines the campaign message and communicates it to the voters. The party raises the money to fund the campaign, does the polling necessary to understand what the electorate is thinking, and structures the campaign strategy and tactics. Typically full-time, year-round party workers perform all these functions or they are contracted out to professionals.

Where strong party systems do not exist, individual candidates must build their own organizations. In these cases, candidates are most concerned with their own elections, not that of those who share this party label. Candidates choose campaign managers whose sole goal is victory for that one candidate. They build personal organizations to handle the important functions of campaigning – doing research to develop issue positions and to counter opponents' proposals; polling the public to ascertain perceptions of the candidate and reactions to strategies; writing speeches; communicating with the press; developing and placing advertisements; sending out direct mail appeals, telephoning and leafleting the district; scheduling and preparing for candidate appearances; and perhaps most important, raising money. For larger and more expensive campaigns, all of these functions are performed by paid workers or volunteers in a candidate's own organization, or bought with campaign contributions.

Recent campaign organizations have been less able to handle all of these functions, and two means of coping have emerged. For campaigns in smaller constituencies, the candidate often performs all of these functions him or herself. They are done more or less well depending on the skill of the candidate, the time available, the level of competition, and the sophistication that is expected in campaigning for office (Maisel, 1999).

Even those with relatively high budget campaigns often find that they cannot hire staff to perform all of the necessary campaign activities. These candidates frequently turn to paid political consultants, experts from outside the campaign who specialize in certain aspects of the campaign process and sell their services to many campaigns during any election cycle. Firms specialize in media advertising, polling, direct mail, telephone banks, fundraising, and virtually every other aspect of campaigning; other firms are structured to take over all or many aspects of a campaign. Some work in particular geographic areas. Others are ready to sell their services anywhere throughout an entire nation or even internationally.

Defining Messages and Setting Strategy

A political campaign requires getting a message to voters. To do that, a candidate must define what the message is and must devise a strategy to reach the voters who will be swayed by that message. Again, how this is to be done varies with whether the campaign in question is party-centered or candidate-centered.

For party-centered campaigns, the message is the party platform, and the voters to be reached at those in the party's core constituency and others to whom the message might appeal in a particular year. Neither the message nor the strategy vary much from year to year, though marginal changes are made as the context changes – and these marginal changes might well spell the difference between victory and defeat.

For candidate-centered campaigns these decisions are among the most crucial. Candidates must decide whether to stick with the party message or to devise one of their own; they must decide what particular issues will play best to their voters; and they must figure out who precisely those voters are. Campaign strategists divide the electorate in a variety of ways – by demographic characteristics, by economic interests, by geographic locations. The goal is to use research and polling data to determine what appeals will work with which audiences and to have the candidate address those audiences appropriately. For incumbents seeking re-election, the strategic consideration often involves relying upon strengths demonstrated earlier. For challengers, the strategy must be to find an opponent's weakness and to emphasize one's own strengths.

Effective campaign strategies remain more art than science. Professional political campaigners know what has worked in the past. But many strategists learn those lessons. The successful strategists are those who can see how to change the approach as the context changes, as is often said in the military, 'not to refight the last war but to plan for the next one.'

Communicating with the Voters

To be effective, a political campaign must be able to send the message it has devised to the audience it has targeted. Campaign messages are communicated in two ways, through free media and paid media.

Free Media Coverage

Political campaigns seek free media coverage in whatever form they can, whenever they can. Candidates want to be reported on in newspapers and newsmagazines; they want to grant interviews on radio; they want their events covered on television. Free media coverage is advantageous not only because there is no cost but also because the viewer sees news coverage of a candidate as giving that candidate a sense of legitimacy; the candidate is seen as part of the day's news, not as part of a paid advertisement. However, free media is uncontrolled exposure. Campaign strategists can try to structure what topics will be covered – and campaigns are exploring increasingly sophisticated means to do this – but too frequently the message delivered is very different from the message the candidate seeks to convey.

Paid Media Advertising

The opposites apply to paid advertising. Paid media – whether in the form of television, radio, or print advertisements, of Internet sites, or of direct mail – is costly and is often viewed by the prospective voter as the slanted message it in fact is. However, these paid media also have the distinct advantage of allowing a candidate to emphasize exactly the message desired. These messages can be narrowcast, that is designed for and directed to specific target audiences. These ads can create images, discuss positions, or – increasingly in recent years – attack an opponent, all in precisely the way strategists feel will be most effective for a specified audience.

The critical concerns about political campaigns today relate to paid media. Many fear that effective political messages cannot be conveyed in 30-second advertisements, the medium preferred by advertising executives. Others complain that the emphasis on negative, attack advertising has poisoned the atmosphere that surrounds political life, keeping some of the best candidates from running (Ansolabehere and Iyengar, 1995). Virtually everyone bemoans the exorbitant costs of campaigns, costs spurred by reliance on paid media. However, political campaigns will continue to rely on paid media so long as they are effective in communicating a candidate's message to the target audience; for that is the means to electoral success – the ultimate message of a campaign's effectiveness.

Editor's Note

Recent research on political campaigning has focused on two major themes: (1) uses of social media and Internet communicaitons in political campaigns; and (2) comparative international studies of campaigns, strategies and effects. One interesting and recent study combining these two interests is Lilleker and Jackson, 2011. Also of interest: Vergeer et al., 2013; Vergeer, 2012.

Abstract

Donald T. Campbell (1916–96), American social scientist. Campbell received his B.A. and his Ph.D. at the University of California (Berkeley). Though he taught initially at the University of Chicago and later at several other institutions (Syracuse, LeHigh), Campbell spent the vast majority of his scholarly years (1953–79) in the Psychology Department at Northwestern University with which Campbell is 'permanently and inextricably co-identified.' Social psychology was his home base, but Campbell also influenced a vast array of other disciplines (philosophy, anthropology, sociology, statistics, education, and political science among them), scholars, and students through his seminal methodological and theoretical writings. He also insisted on exploring the connections among and interstices between disciplines as legitimate and often ignored areas for scholarship and debate. His emphasis was always on the acquisition of knowledge, and particularly on the fallibility of any single method or observation as a representation of reality. From those basic points, Campbell developed an enormous volume of rich concepts ('triangulation,' 'convergent vs discriminant validity,' 'plausible rival hypotheses,' 'evolutionary epistemology,' 'heterogeneity of irrelevancies') and practical strategies ('quasi-experiments,' 'unobtrusive measures') which have influenced dramatically both individual scholars as well as the current direction of the social sciences. Working simultaneously on basic epistemological and practical measurement and political issues confronting many disciplines, Campbell's contributions were fundamental and multirfaceted. With a twinkle in his eye and a gift for precise but colorful language, Campbell collaborated generously with generations of students and colleagues to produce some of the most oft-cited and influential work in twentieth-century social science.

Donald Thomas Campbell, born 20 November 1916 in Grass Lake, Michigan, died 6 May 1996 in Bethlehem, Pennsylvania, thus ending a career marked by an array of superlatives. Prolific scholar and author, original thinker, ebullient teacher with a notable twinkle in his eye, and generous colleague, Campbell was widely regarded as the most important social science methodologist of the twentieth Century. Several of Campbell's articles vie with one another as among the most widely cited pieces of social science scholarship. Repeatedly he coined phrases any one of which most scholars would be proud to have conceived, for example, 'quasi-experiments,' 'unobtrusive measures,' 'internal and external validity,' and 'plausible rival hypotheses.' His concepts are incorporated as fundamental in several fields – psychology, sociology, anthropology, organization and management sciences, public policy, evaluation, education, and philosophy – and in common use by scholars unaware of their inventor. Moreover, Campbell's welcoming and self-critical personal style, modeled on his scholarship, led him to embrace and examine all 'plausible rival hypotheses' and endeared him to students and colleagues alike.

Campbell received his B.A. (1939) and Ph.D. (1947), both in Psychology, from the University of California (Berkeley), and taught at several institutions, including Ohio State University (1947–50), the University of Chicago (1950–53), Syracuse University (as N.Y. State Board of Regents Albert Schweitzer Professor, 1979–82) and Lehigh University (as Distinguished University Professor of Sociology-Anthropology, Psychology and Education, 1983–96), but the majority of his scholarly years were spent as professor of psychology at Northwestern University (1953–79) with which Campbell's name and reputation are 'permanently and inextricably co-identified' (Campbell, 1981).

Campbell's honors include a Fulbright Visiting Professorship in Social Psychology at Oxford (1968), the Distinguished Scientific Contribution Award from the American Psychological Association (1969), election to the National Academy of Sciences and the American Academy of Arts & Sciences (1973), the Kurt Lewin Memorial Award from the Society for the Psychological Study of Social Issues (1974), presidency of the American Psychological Association (1975), the Williams James Lectureship at Harvard (1977), the Myrdal Prize in Science (1977), and the Distinguished Contribution Award from the American Educational Research Association (1981). In addition, two annual awards are given in his name: The Donald Campbell Award for Significant Research in Social Psychology (1982–) and the Donald Campbell Award from the Policy Studies Organization, to an 'outstanding methodological innovator in public policy studies' (1983–). Campbell received honorary degrees from numerous universities, including Oslo, Michigan, Chicago, and Southern California.

But Campbell felt most honored by the vast array of books dedicated to him, a list that grew steadily in several disciplines before and after his death.

Major Contributions

When he died, Campbell's resumé listed more than 230 published books, monographs, and articles. Any brief discussion of his contributions must necessarily focus on a few. Best known as a methodologist, with considerable scholarly work in the areas of experimental design, measurement, and social experimentation, Campbell is perhaps remembered especially for his explorations of the concept of validity. He was also a well-regarded epistemologist with a keen interest in the sociology of science. To each domain, Campbell brought his unique mind to bear on the problem of knowledge production. In a remarkable array of works, Campbell explored from several

perspectives the inevitable fallibilities inherent in both observers and methods in accurately portraying the world.

In his earliest publication, 'The Indirect Assessment of Social Attitudes' (1950), Campbell evidenced an aspect of the interests that would become the overall focus of his scholarly life: the imperfections introduced by human observers and methods, including the scientific method, in the search for veridical description of the physical world and mechanisms for compensating for these errors. (Campbell later declared profound 'ambivalence' toward the use of disguised measures; see Kidder and Campbell, 1970.) Campbell explored the sources and loci of bias and developed and refined methods for illustrating and for minimizing these biases. For example in Jacobs and Campbell (1961) he demonstrated how consensus in the 'reality' of an arbitrarily invented but shared group norm could persist over generations of experimental subjects. In a series of crosscultural explorations Campbell and co-workers (e.g., Segall et al., 1966) explored sources of validity and invalidity in perceptions of 'in-groups' and 'out-groups,' and the differential susceptibility to perceptual illusions between European and non-European cultures.

Campbell and Fiske (1959) published 'Convergent and Discriminant Validation by the Multitrait, Multimethod Matrix,' a complex and frequently cited analysis of the need for multiple measures of underlying constructs (traits) and of the need for the demonstrated capacity of methods to distinguish among traits if one is to minimize irrelevant measurement artifacts. Since every measure is partially invalid, multiple and distinctive methods are called for to yield a 'heterogeneity of irrelevancies.' Campbell and Fiske explored the value of simultaneously deploying maximally different measures of an underlying trait (in pursuit of convergent validation) and of different traits measured the same way (in pursuit of discriminant validation). Only by demonstrating that an underlying trait can be measured in various distinct ways and that the chosen measurement strategies distinguish among measured traits, can one minimize the impact of misleading artifacts.

By the early 1960s Campbell had established an enviable reputation for the vigor and reach of his campaign for advancing the methods and theory associated with issues of validity. His reputation was further advanced with the publication with (Campbell and Stanley, 1963) of 'Experimental and Quasi-experimental Designs for Research,'a widely circulated work (elaborated as Cook and Campbell, 1979) in which they popularized the terms 'internal' and 'external' validity:

> Internal validity is the basic minimum without which any experiment is uninterpretable: did in fact the experimental treatment make a difference in this specific experimental instance? External validity asks the question of generalizability: To what populations, setting, treatment variables, and measurement variables can this effect be generalized? (Campbell and Stanley, 1963).

Another widely cited treatise, *Unobtrusive Measures: Nonreactive Research in the Social Sciences* (Webb et al., 1966) evolved during affable lunchtime conversations with colleagues from different departments. Over several years these colleagues sought to identify relatively unbiased, nonreactive ways of measuring behavior. A frequently cited example describes ways a Chicago museum tried to identify the popularity of its exhibits. 'Obtrusive measures' included questioning visitors leaving the museum; an 'unobtrusive measure' was the frequency with which museum staff had to replace worn tiles in front of exhibits. By that index, the exhibit of baby chicks hatching live and wet from quivering eggs was by far the most popular.

Campbell's participation in an interdisciplinary conference spawned his brilliant foray into the sociology of science entitled 'Ethnocentrism of Disciplines: A Fishscale Model of Omniscience' (1969a). On reading a paper 'in an area of high relevance' to his own work by esteemed fellow social psychologist William McGuire, Campbell realized and then acknowledged that he had not 'read or read-at even half of McGuire's citations, and was not at all aware of the existence of another sizeable proportion' (Campbell, 1969a). While many scholars might react with chagrin, Campbell instead reflected on how the 'highly arbitrary' organization of universities and academic fields skewed knowledge production:

> Thus anthropology is a hodgepodge of all novelties venturing into exotic lands – a hodgepodge of skin color, physical stature, agricultural practices, weapons, religious beliefs, kinship systems, history, archeology, and paleontology ... Thus psychology is a hodgepodge of sensitive subjective biography, or brain operations, or school achievement testing, of factor analysis, of Markov process mathematics, of schizophrenic families, of laboratory experiments on group structure in which persons are anonymous ... Thus economics is a hodgepodge of mathematics without data, of history of economic institutions without mathematics or theory, of an ideal model of psychological man... (Campbell, 1969a)

Campbell took a breathtaking leap when he conceived the 'myth of unidisciplinary competence,' demonstrating how social, administrative, structural, and political supports which accrue over time around arbitrary disciplines ultimately create incentives that reinforce these arrangements and punish others of equal epistemological worth. Campbell detailed the inevitable consequence–biased knowledge production – and offered a model of 'interdisciplinary narrowness' for mitigating this 'ethnocentrism of disciplines.'

By the late 1960s, following Vietnam War protests, campus unrest, and a national focus on urban inequities, Campbell began trying conscientiously to influence the design, implementation, and evaluation of social policies. In 'Reforms as Experiments' (1969b) Campbell introduced a range of real-world quasiexperiments (attempts to approach the standards of experimentation even where random assignment of subjects to conditions is unachievable) – each tested against standards of 'internal and external validity' – to the practical world of social reform. That article frequently is cited as the most important single work in the field now known as 'program evaluation.'

In a brilliant tongue-in-cheek section of this article Campbell advised 'trapped administrators whose political predicament will not allow the risk of failure' how to capitalize on 'threats to validity' to assure positive results (Campbell, 1969b). For example, were they to accept the occasional 'grateful testimonial' as if it were a representative outcome, to

reserve interventions for carefully selected subpopulations most likely to succeed, and to eliminate from their analyses all those who prematurely quit the program, 'successful' program outcomes could be virtually assured.

Campbell continued in various fora to insist that social scientists have both obligations and opportunities to test the relevance of their theories and methods in the service of public good. In this, Campbell's unswerving concern was with the biases affecting the generation of knowledge. For example, in his too-infrequently cited 'Assessing the Impact of Planned Social Change' (1975) Campbell again displayed remarkable methodological and sociological insight in generalizing the problem of data validity in the policy arena in the following way:

> The more any quantitative social indicator is used for social decision-making, the more subject it will be to corruption pressures, and the more apt it will be to distort and corrupt the social processes it is intended to monitor (Campbell, 1975).

Corrupted indicators remain a persistent and only vaguely explored source of real-world invalidity (e.g., Cochran et al., 1980).

Another highly influential, widely circulated piece went unpublished for nearly 20 years: in 'Methods for the Experimenting Society' Campbell attempted specifically to design a strategy for a society willing to test innovations and their intended effects. He argues for a society that would

> vigorously try out possible solutions to recurrent problems and would make hard-headed, multidimensional evaluations of outcomes, and when the evaluation of one reform showed it to have been ineffective or harmful, would move on to try other alternatives (Campbell, in Overman, 1988).

Surveying the multitude of societal reforms underway at the time, many of which he endorsed (e.g., Alexander Dubcek in Czechoslovakia, Salvador Allende, in Chile), Campbell argued:

> There is no such (experimenting society, committed to reality testing, self-criticism, to avoiding self-deception) anywhere today. While all nations are engaged in trying out innovative reforms, none of them are yet organized to adequately evaluate the outcomes of these reforms (Overman, 1988).

After specifying requirements of such an 'experimenting society' Campbell attempted in various ways to determine conditions under which these results might be achievable. For example, after Allende was assassinated in Chile, Campbell invited Chilean social scientist Ricardo Zuñiga to Northwestern University specifically to reflect on the conditions that might allow vigorous, large-scale reforms to be tested.

Campbell made other major contributions in his application of evolutionary theory to the realm of ideas. Campbell, the eternal epistemologist, focused in particular on the joint operation of the 'blind-variation-and-selective-retention process fundamental to all inductive achievements, to all genuine increases in knowledge.' In his 'evolutionary epistemology,' which perhaps received its fullest flowering in his essay honoring Karl Popper (in Overman, 1988), Campbell endorsed the natural selection paradigm for explaining the production of knowledge. Through the selective winnowing of ideas, Campbell argued, what survive over time are those ideas that are most meritorious, particularly as each is subjected to 'critical realism.' In his William James lectures, Campbell (1977) summarized his perspective in this way:

> I am a fallibilist and antifoundationalist. No part of our system of knowledge is immune to correction. There are no firm building blocks, either as indubitable and therefore valid axioms, or in any set of posits that are unequivocal once made. Nor are there any unequivocal experiences or explicit operations on which to found a certainty of communication in lieu of a certainty of knowing.

> I am some kind of a realist, some kind of a critical, hypothetical, corrigible, scientific realist. But I am against direct realism, naive realism, and epistemological complacency (Campbell, in Overman, 1988).

Legacy

Campbell's legacy is vast and pronounced. It affects a wide range of social scientists as well as public policy scholars and practitioners, and is reflected in the work of hundreds of his students and more distant heirs. He introduced fundamentally new ways of thinking that are taken for granted today about how we perceive, discover, and assess accumulated knowledge. Many of his concepts are now fundamental throughout the social and policy sciences. Campbell is the most important intellectual figure in the history of evaluation research. The strategies he employed in 'Reforms as Experiments' for unearthing and illustrating threats to interpretations of policy implementation are an often-cited model for exploring complex data (see Tufte, 1983).

In remarkably vivid, fetching but precise language, Campbell repeatedly captured the central importance of fallibilities inherent in human observers and their methods as they accumulate knowledge about the world, and thus of the importance of multiple perspectives, the triangulation of methods, and an open process whereby ideas are tested against one another to promote the winnowing effects of competition. Thus, in the James lectures, Campbell stated that

> We are cousins to the amoeba, and have received no direct revelation not shared with it. How then, indeed, could we know for certain? ... Our only hope as competent knowers is that we be the heirs of a substantial set of well-winnowed propositions (Campbell, in Overman, 1988).

In the heady intellectual mix he created and sustained, Campbell was known for changing his mind when persuaded by carefully tested evidence, and for challenging others to do the same. For example, over the years Campbell was persuaded

by sociologist Howard S. Becker and others to appreciate the falsifiability of carefully wrought case studies, in spite of their failure to live up to his long-cherished methodological criteria (Campbell, in Overman, 1988). In return, he prompted qualitatively-oriented colleagues to persist in reconsidering the validity claims inherent in their own work (see, for example, Becker, 1986). For this open-mindedness, Campbell is revered by quantitative and qualitative methodologists alike (see Patton, 1999).

Campbell also influenced legions of colleagues to reflect honestly on their own work. He talked and wrote openly about his own insecurities and frustrations, including how late in his career he began to write, droughts in his own productivity, his discomfort with the production pressure and relentless expectation of genius when he was a young assistant professor at the University of Chicago, his frequent bouts of depression, and the times when he believed his students and colleagues 'carried him.'

He explained his messy desk cheerfully by saying that he 'filed archeologically,' and as long as no one moved things around he could find whatever he wanted. Amazed colleagues would watch him reach into a pile and pull out the precise papers relevant to their discussions.

Although its publishers have sold thousands of copies of *Experimental and Quasi-Experimental Designs for Research* and students return to it year after year, Campbell never received any royalties; he asked only for unlimited copies to give freely to his colleagues.

Consideration of Campbell's legacy would be incomplete without a discussion of his personal style, for it, too, promoted the production of knowledge while providing his colleagues with a vital and successful paradigm. It would understate Campbell's colossal influence if there were no mention of his towering warmth, kindness, and generosity, and his deeply honest and self-critical perspective on his own work (Campbell, 1981). Campbell was remarkably able to reflect on his own fallibilities and to create conditions that would model his epistemology, and improve both his work and the work of others. Examples are diverse and legendary: he would often send a requested reprint accompanied by a colleague's critical rejoinder. He was always in pursuit of contrary evidence and counter-intuitive examples, particularly if they confronted his own work. He encouraged students to write minority sections to project reports if they disagreed with him or with an emerging majority. Campbell was resolutely encouraging of others and in fact was thought by some to 'suffer fools gladly.' He gave three grades: A, B, and incomplete. If the data collected in dissertations failed to support anticipated hypotheses, or failed to replicate published findings in the literature, Campbell urged students to write up the apparent reasons for the obtained results.

Over time, Campbell connected his early deep philosophical explorations to a program of practical work that will continue to guide generations of scholars and practitioners. Campbell lives on through his voluminous work in many fields, through his students, and through their adoption of his style.

Abstract

With advances in treatment efficacy and improvements in survival rates, cancer is increasingly viewed and treated as a chronic disease that can be effectively managed for many years. From the onset of symptoms until the completion of therapy and into survivorship, patients face different physical, psychological, and social challenges. In addition, not only patients but also their partners have to deal with the consequences of cancer. Significant advances have been made in the understanding of psychosocial adjustment to cancer. Routine screening and management of psychosocial distress with psychosocial interventions is recommended as an integral part of cancer care. Moreover, the interactions between patients and family members are of great importance to further the field by providing more insight into the family dynamics of dealing with cancer.

Psychological Distress

An aging and growing population is associated with more elderly patients being treated for cancer. Remarkable advances have been made in innovative medical technologies and therapies for cancer patients. Almost 60% of adult cancer patients are expected to survive at least 5 years from diagnosis or to be cured, with 2/3 of them over 65 years of age (Valdivieso et al., 2012). The number of people treated or followed up for cancer or who have survived the disease, therefore, is growing. Nevertheless, cancer remains a life-threatening diagnosis with profound psychosocial impact even years after medical treatment has ended. Cancer patients are known to endure psychosocial, emotional, and physical distress. Psychosocial distress describes an unpleasant psychological (behavioral, emotional, cognitive), social, and/or spiritual experience, which can negatively impact cancer patients' ability to cope effectively with cancer, its physical symptoms, and its treatment (Pirl et al., 2014). Moreover, prolonged exposure to stress can have a negative effect on quality of life (QoL) and results in a host of physical symptoms. In the light of such substantial and sustained disease burden, the management of survivorship issues in cancer assumes paramount importance. Such issues revolve around the effective maintenance of individual functioning (e.g., psychological distress, QoL) throughout the course of cancer. The research base evaluating the prevalence of psychological burden (such as depression and anxiety) is growing steadily, and there is now also a sizable body of clinically relevant research.

Psychological Distress in Cancer Patients

Psychological distress covers a wide spectrum, ranging from normal feelings of vulnerability, sadness, and fears to problems that can become disabling, such as depression, anxiety, extensive worries, negative thoughts, or social isolation. The prevalence of distress, depression, anxiety, and other psychiatric disorders has been studied for many types and stages of cancer. A recent review shows a prevalence of 38.2% of mood disorders in patients with various types of cancer (Mitchell et al., 2011). Significant distress ranges from 20% to 40% in newly diagnosed patients, as well as patients experiencing a recurrence (Holland et al., 2010). Distress is associated with higher rates of nonadherence to medical treatment, QoL, or even survival (Shimizu, 2013). In cancer care, patients' distress levels have been positioned as the sixth vital sign in addition to heart rate, respiration, blood pressure, temperature, and pain (Bultz and Carlson, 2006). Psychological distress may include physical and cognitive dysfunctions resulting from cancer treatment, anxiety and depression, disruptive social and dyadic relationships as well as fatigue and sleep disturbances. Patients experience significant disruptions to normal daily activities, which challenge a person's assumptions about their current and future life trajectory and sense of self. Patients have to cope with role changes and distress provoked by the increase in functional disability and physical side effects associated with cancer and its medical treatment. Some cancer patients blame themselves for the cancer diagnosis (e.g., head and neck cancer patients due to the fact that tobacco and alcohol represent the major risk factors for these cancers (Lang et al., 2013)). Moreover, long-term cancer survivors worry about cancer recurrence or development of new cancers, as well as physical, cognitive, socioeconomic, sexual, and legal issues (Valdivieso et al., 2012).

Depression and Anxiety

Distress in cancer patients can also precede clinical depression and anxiety, with prevalence rates ranging between 5% and 50% (Artherholt and Fann, 2012). A recent meta-analysis found mood symptoms in all patients (men and women) and at all stages of treatment (palliative and nonpalliative; Mitchell et al., 2011). In identifying depression, some symptoms such as low mood, loss of interest in usual activities, feelings of hopelessness or guilt, or suicidal ideations are particularly important to consider whereas physical symptoms such as appetite and weight loss, fatigue, and sleep disturbances may overlap with disease or treatment effects. Depression should carefully be distinguished from sadness or grief. Numerous patients that receive a cancer diagnosis assume that they are close to death and experience anxiety, depression, fear, and anger as the disease progresses.

Fear of Recurrence

A widespread problem among cancer patients in addition to psychosocial burden and physical symptoms is the fear of

recurrence (FoR). FoR is defined as the fear of the disease recurring or progressing in the same organ or a different area of the body. FoR is negatively associated with QoL and psychosocial well-being, inducing depression, and anxiety (Herschbach et al., 2005). Specific situations and/or symptoms (e.g., aftercare appointments, anniversaries of the diagnosis, or environmental triggers) can activate the intensity of FoR. Hence, estimates of prevalence rates depend on the time of assessment. A recent systematic review shows that even years after the initial cancer diagnosis, cancer survivors still experience FoR with modest intensity (Koch et al., 2013). This implies that FoR can persist over an extensive period of time after the initial cancer diagnosis in unchanged intensity. Moreover, FoR was also found in partners of cancer patients (Zimmermann et al., 2011).

Cognitive Dysfunction

Problems with memory, attention span, or concentration in cancer patients who received chemotherapy are known as chemotherapy-related cognitive dysfunction, also known as "chemobrain" or "chemofog." Between 4% and 75% of patients are affected by these problems, and for 20–35% of cancer survivors, it may persist for months or years after treatment has been completed (Hines et al., 2014). Although the causes for these cognitive deficits remain unknown, they can have a considerable negative impact on QoL and functional ability (e.g., work-related difficulties, social withdrawal for fear of deficits being noticed).

Sexual Impairment

Almost any cancer diagnosis can lead to sexual impairment, those directly affecting areas related to sexual function are particularly concerned (e.g., breast or genitals). Among cancer survivors, sexual dysfunctions are common, but often not addressed. Side effects of the medical treatment (e.g., chemotherapy, radiation, and hormone therapy) can contribute to lower self-esteem, depression, less desire for sexual activity, and lower libido. Sexual disturbances are frequent among cancer patients regardless of gender, and need attention by health care providers (Valdivieso et al., 2012). It is also important to recognize that psychosocial aspects as depression or anxiety can contribute to sexual dysfunction (specifically in terms of desire, arousal, and orgasm). In women with cancer (i.e., breast cancer) the iatrogenic menopause can cause significant detriment to sexual functioning (e.g., lowered libido, decreased vaginal lubrication, dyspareunia, and numbness in previously sensitive breasts; Morreale, 2011). Comparable results were found for the iatrogenic effects of hormonal ablation in men with prostate cancer, which include mood disturbance, cognitive impairment, fatigue, and sexual dysfunction (Chambers et al., 2011). Cancer patients with a negative view of their body after cancer treatment have been found to have lower rates of sexual satisfaction. For example, patients with colorectal cancer and newly formed enterostoma experience disturbances in body image and may face complications such as leakage, skin and stoma problems, and odor, which may lead to low self-esteem, poor self-concept, and sexual dysfunction (Hoon et al., 2013). In addition, the relationship between the cancer patient and the partner is an important factor for sexuality. For example, for breast cancer patients, the quality of the relationship emerged as a strong predictor of sexual functioning (Gilbert et al., 2010).

Body Image

Cancer patients often have to cope with significant changes to appearance and functioning. Body image is, therefore, a critical psychosocial issue for these patients. Cancer and its medical treatment can profoundly affect patients' body image during various stages of treatment and have strong implications for psychosocial adjustment and social-functioning. For example, patients with serious body image concerns experience negative emotions (i.e., distress), avoid social situations, and become isolated. Independent from cancer or its site, a negative body image adversely impacts QoL and psychosocial-functioning (e.g., anxiety and depression, and sexual functioning). Cancer and its medical treatment can lead to appearance changes (i.e., scarring, hair loss, disfiguration), sensory alterations (e.g., numbness, pain), and functional impairment (e.g., dysphagia, impotence, dysarthria). Problems with body image occur in patients with different cancer sites, which are most prevalent in the immediate postoperative and treatment period (Fingeret et al., 2014), and involve perceptions, thoughts, feelings, and behaviors related to the whole body and its functioning. Only few studies have investigated the prevalence rates of body image concerns in cancer patients; however, there is some evidence that patients with head and neck cancer show the highest prevalence rates of up to 75% (Fingeret et al., 2014), primarily due to surgical disfigurement and obvious changes in their appearance, or changes in how they speak and eat (Lang et al., 2013; Semple et al., 2013). In addition, patients with colorectal cancer experience body image disturbance after surgery (enterostoma), which may be associated with greater distress and poorer QoL. Nevertheless, further investigations are necessary to confirm these associations (Sales et al., 2014). Other studies have focused on the prevalence of body image concerns in women with breast cancer and found prevalence rates between 17% and 33%. Also, long-term breast cancer survivors' rates range between 15% and 30%. In summary, body image concerns affect a substantial number of patients with cancer, which may persist into long-term survivorship. Further research is necessary to identify demographic, disease, and treatment-related factors that increase the risk for body image concerns.

Positive Aspects

Despite the negative consequences of a cancer diagnosis, a growing literature also reports positive aspects of the cancer experience such as greater appreciation of life, changed priorities, closer relationships, and enhanced spirituality. In a study by Dorval et al. (2005), 42% of the 282 couples with women newly diagnosed with nonmetastatic breast cancer, reported getting closer together after the cancer experience. Cancer can be a growth experience for patients and couples (Tedeschi and Calhoun, 1995), in terms of (1) benefit finding (e.g., positive change in relationships, greater appreciation of life, and change in priorities), i.e., the acquisition of benefit from adversity, and (2) posttraumatic growth (e.g., increased sense of personal strength, changed priorities, and richer existential and spiritual life), i.e., success in coping with the aftermath of a trauma,

reconstructing or strengthening perceptions of oneself, others and the meaning of events (Tedeschi and Calhoun, 2004).

Psychological Distress in Partners of Cancer Patients and the Couple

There is growing awareness that cancer not only affects patients, but also the entire family, friends, and caregivers. Usually the patient's intimate partner is the primary caregiver. The diagnosis and treatment of cancer can affect both members of the dyad, and induce serious distress and negatively impact successful coping throughout the cancer trajectory (McClure et al., 2012). Social relationships are among the most-studied contributing factors to QoL in cancer patients (Stanton et al., 2007). Among these relationships, the patient's relationship with the spouse is considered paramount because cancer patients identify their partners as their most important source of emotional and instrumental support (Baanders and Heijmans, 2007). The diagnosis and treatment of cancer, however, can affect every aspect of both patients' and partners' psychological functioning. Partners and patients can show higher levels of distress compared to the general population (Hinnen et al., 2008; Nakaya et al., 2010). For a long time, cancer was considered an individual stress experience demanding individual coping strategies. Since both partners of the dyad interact with and mutually influence each other, it is important to consider the individual and dyadic functioning of the patient in relation to the partner's physical and mental states, and vice versa. The intercorrelation between the psychological distress of patients and spouses support the interdependence between patient and partner (Hagedoorn et al., 2008). Therefore cancer should be considered as a stressor concerning both partners simultaneously and should be studied as a couple's disease if a partner is present (Kayser et al., 2007).

Cancer not only impacts the patients' life in demanding restoring physical, psychological, and social homeostasis, but also threatens the spouse (Traa et al., 2014). Both the patients' and the partners' reactions to a cancer diagnosis include fear, uncertainty, anxiety, and depression with patients' partners' reactions mutually determining how they cope with and adjust to the illness. The partner has to adapt to the patients' disease, has worries, has to confront the potential loss of a life partner, is burdened by taking over the patients' tasks, and by providing support and caring. Moreover, spouses can experience important restrictions in their social life, and interruption to daily life; they might suffer from economic or financial consequences, have to manage household and child care responsibilities, and are threatened by an insecure future (Traa et al., 2014). Sleep disturbances, fatigue, loss of physical strength, pain, loss of appetite, and weight loss are the most prevalent physical problems in caregivers (Stenberg et al., 2010). Prevalence of depression and anxiety among partners of cancer patients varies between 10–53% and 16–56%, respectively (Girgis et al., 2013). Several studies demonstrate disruptions in social involvement and activities of the partners due to their caregiving responsibilities (Girgis et al., 2013).

In addition, cancer-related stress contributes to general life stress and daily hassles. Partner experiences a 'double role': on the one hand they undergo their own psychosocial distress, and on the other hand they have to provide support during a time when they themselves are under extreme stress. Therefore, coping with cancer can challenge communication patterns, roles, and responsibilities of a couple. While the majority of partners dealing with cancer experience a variety of psychosocial burden, many caregivers report also positive emotions (e.g., satisfaction, happiness about quality time with the spouse, feelings of value and self-worth) from their caring role (Girgis et al., 2013). Not surprisingly, some couples report that the cancer experience brought them closer together (cohesion), whereas others experience adjustment and communication problems that may result in decreased intimacy and lower relationship satisfaction.

There is emerging evidence that dyadic processes, specifically communication and dyadic coping, may be involved in the adjustment process for both partners when facing a cancer diagnosis. Under the stressful circumstances of the diagnosis, couples may tend to be kind to each other (increase positivity in the relationship), but this may occur within the context of avoidance (e.g., not talking about the stressor, mutual withdrawal to give the other person time to adapt, and not upsetting the other person). Thus, despite an increase in positive interaction between partners at present, such avoidance patterns potentially come at the cost of not addressing the issues surrounding the illness, which places long-term adjustment to cancer and relationship satisfaction at risk (Manne et al., 2010). This phenomenon, known as 'protective buffering' (i.e., hiding concerns, denying worries, and avoiding discussions), is associated with higher levels of patient and partner distress. Investigating specific dyadic behaviors in couples coping with cancer may, therefore, be more fruitful than relating cancer adjustment to more general marital quality. Lafaye et al. (2014) conclude that coping strategies used by cancer patients or spouses not only influence their own well-being but also the well-being of the partner. Especially, dyadic coping as a stress management strategy entails that both partners are mutually involved in the stress coping process in providing and receiving support from each other and engaging in joint problem-solving activities, and shared emotion regulation to behave as a unit rather than as individuals (Bodenmann, 1995; Badr et al., 2010).

In summary, both members of a couple facing a cancer diagnosis experience psychosocial distress, which might also impact their individual and relationship functioning. Coping with cancer from a couple-based perspective as a dyadic situation demonstrates potentially beneficial effects on psychosocial adjustment and relationship functioning of patients and spouses (Badr and Krebs, 2013; Martire et al., 2010; Regan et al., 2012).

Psychosocial Interventions

The field of psycho-oncology has progressed over the last 40 years from mapping the extent and severity of psychological distress in cancer patients, through the development and evaluation of psychosocial intervention to the current phase of disseminating psychological skills to health care professionals (Moorey, 2013). Over the past few decades, a variety of psychosocial interventions has been developed to address the

psychological and social (i.e., psychosocial) aspects of disease for cancer patients. These interventions involve a wide range of components, such as psychoeducation, enhancing coping skills, and providing supportive care to cancer patients to address the psychosocial needs of cancer patients. Research has shown that treatment of distress may improve health-related QoL in cancer patients (Artherholt and Fann, 2012).

Interventions for Patients

While unmet psychosocial needs exist across cancer types and the cancer care continuum, most studies of psychosocial interventions have been conducted in patients with breast or prostate cancer, and only few studies included patients with late-stage cancer and cancer survivors (Subnis et al., 2014). A large number of patients continue to live with cancer following their surgical and other adjuvant treatments. Consequently, it is necessary to provide also interventions that focus on long-term benefits in patients' adjustment and coping (Tamagawa et al., 2012).

Longitudinal studies are, therefore, needed that include patients from the time of diagnosis until the end of survivorship in a variety of cancer populations, which will provide valuable information about psychosocial aspects and effects of psychosocial interventions across the cancer care continuum. In addition, distress is often underrecognized by medical staff in clinical oncology setting. Inadequate recognition and treatment for distress can interfere with medical decision making and treatment adherence. In 2015, cancer centers in the US will be required to implement screening programs for psychological distress as a new criterion for accreditation (Pirl et al., 2014). Screening is an optimal strategy for detecting problems such as distress in cancer patients. In addition, the National Comprehensive Cancer Network guidelines recommend regular screening for distress with brief screening instruments (e.g., the Distress Thermometer) because of the substantial consequences of disregarded and untreated distress in cancer patients (Holland et al., 2011).

Interventions for Couples

A cancer diagnoses poses many challenges for both patients and their partners. Several reviews have addressed the potential of couple-based interventions to improve individual and dyadic functioning of couples coping with cancer, and the beneficial effects on psychosocial adjustment and relationship satisfaction (Badr and Krebs, 2013; Martire et al., 2010; Regan et al., 2012). Therefore, both patients and their partners should be included in psychosocial interventions, with the aim to support and strengthen their ability to cope with cancer. To date, several couple-based intervention studies aimed at improving dyadic coping and relationship satisfaction of couples coping with cancer. A recent review illustrates the importance of stress communication (e.g., expressing worries, feelings, and needs regarding cancer- or relationship-related topics), supportive behavior, and effective dyadic coping for relationship satisfaction in couples coping with cancer (Traa et al., 2014). Moreover, interventions with multiple targets, e.g., reduction of emotional distress, improved communication and sexual intimacy, and strategies to enable partners to express their distress show the most promising results in enhancing couples' well-being (Wootten et al., 2014). In summary, couple-based interventions have yielded promising results for couples in which one partner has a cancer diagnosis in improving communication, dyadic coping, QoL, psychosocial distress, sexual functioning, and marital satisfaction (Li and Loke, 2014; Badr and Krebs, 2013).

Conclusions

The increase in survival rates of cancer patients suggests that aspects of illness adjustment and QoL are becoming increasingly important. Psychosocial aspects have been examined in patients with different cancer diagnoses and at varying disease stages. Significant impairments in physical-, role-, emotional-, cognitive-, and social-functioning negatively affect QoL and psychosocial adjustment in cancer patients. Cancer patients' psychological distress follows distinct trajectory patterns during the course of the disease. A proportion of patients maintain low psychological distress levels and adequate QoL during the entire duration of the illness, while others show a U-shaped pattern, i.e., initially high stress levels, followed by a gradual reduction as cancer progresses with an increase again toward the terminal stages of the disease. Maintaining and enhancing the well-being of cancer patients is of great importance in cancer care. Further research and improvements are necessary (1) in identifying patients' distress (e.g., with effective screening instruments), (2) in identifying partners' distress, (3) in improving psychosocial interventions (for patients, partners, couples, or families), (4) in offering cancer patients (and their partners) appropriate psychosocial therapies, which suit their psychosocial needs (indicated care), and (5) in integrating psychosocial therapies and services into the standard of quality cancer care. More research is needed to develop more effective methods of identification and targeted interventions for psychosocial aspects in the context of cancer treatment. Clinicians should be aware of the impact of psychosocial aspects on cancer patients, even years after the initial diagnosis, e.g., FoR, anxiety, depression, body image concerns, sexual dysfunction, etc. Therefore, the identification and management of major psychosocial aspects should be a clear clinical priority. Because of the potential of psychosocial aspects to reduce QoL and to induce psychosocial morbidity, even years after the initial diagnosis, the lack of research in this area and an increasing number of long-term cancer survivors, future studies in the field of psychosocial aspects of cancer should focus on these factors, and on effective ways to improve psychosocial adjustment and QoL for cancer patients and their partners.

Cancer Screening

Arja R Aro, University of Southern Denmark, Esbjerg, Denmark

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Cancer is a growing health problem worldwide, mainly due to the expanding elderly population. Screening for cancer aims to reduce cancer mortality and morbidity by targeting asymptomatic people to identify those at increased risk of having either disease or precancerous changes. Screening is an intervention on groups of people who have not demanded the service. This means that benefits and harms of screening programs need to be carefully weighed against each other; these can be studied at societal, service provider, and individual levels. Rapidly developing biomedical knowledge on cancer and screening technology as well as increasingly informed citizens pose challenges for cancer screening programs.

Cancers

Cancer is a generic term for a large group of diseases that can affect any part of the body. Other terms used are malignant tumors and neoplasms. One defining feature of cancer is the rapid creation of abnormal cells that grow beyond their usual boundaries, and which can then invade adjoining parts of the body and spread to other organs. This process is referred to as metastasis. Metastases are the major cause of death from cancer. Typically cancer develops slowly and has a long preclinical or prepathological phase. Cancer screening is based on the assumption that it improves prognosis that the required treatment would be less severe thereby contributing to improved quality of life and savings for the society.

Difference between Screening and Testing

Screening for cancer refers to any kind of test performed for the systematic detection or exclusion of cancer, precancer, or susceptibility to cancer assuming that the *initiative comes from outside the individual*, i.e., from the health care provider or screening organizer. Screening distinguishes apparently healthy people who probably have the target condition from those who do not. The former can then be offered information, further tests and appropriate treatment to reduce their risk and/or any complications arising from the disease or condition. Screening is different from *testing* where the *initiative comes from the individual*, or from a health professional, *in the course of a diagnostic process*. People screened are less prepared for the screening result, less aware about the condition they are screened for, and normally have less contact with medical staff than those being tested. Since screening is aimed at unaware, asymptomatic people, it has heavier public health, social, psychological, and ethical implications than testing.

Rationale for Screening

Using the classical screening criteria by Wilson and Jungner (Wilson and Jungner, 1968) as a basis, several later screening criteria have been synthesized into a general version (Andermann et al., 2008), which accommodates developments in research on biomedicine and technology, especially genetics and genomics but also the growing evidence-base and societal changes reflecting more citizens' influence on policies.

The screening criteria are the following (Andermann et al., 2008):

- The screening program should respond to a recognized need.
- The objectives of screening should be defined at the outset.
- There should be scientific evidence of screening program effectiveness.
- The program should integrate education, testing, clinical services, and program management.
- There should be quality assurance with mechanisms to minimize potential risks of screening.
- The program should ensure informed choice, confidentiality, and respect for autonomy.
- The program should promote equity and access to screening for the entire target population.
- Program evaluation should be planned from the outset.
- The overall benefits of screening should outweigh the harms.

Specific screening guidelines for different cancer types have been developed and updated to be in line with the scientific advancements, growing evidence-base of the screening effectiveness and contextual priorities such as national screening policies. The public health rationale behind cancer screening is to reduce mortality and morbidity of the target condition. According to the present knowledge, for some cancer forms (e.g., cervical cancer, colorectal cancer) precancerous, treatable lesions or changes can be found via screening and thus screening can be preventive. For some other cancers (e.g., breast cancer) the idea is to find cancer in a preclinical asymptomatic phase before it would be found without screening. The assumption is that earlier detection of cancer is beneficial in terms of less invasive (and less costly) treatment, improved survival from cancer and less disruption of quality of life of those screened. Screening for biological markers, such as prostate-specific antigen (PSA) for prostate cancer risk and human papillomavirus (HPV) types for cervical cancer risk, identifies those who have a heightened risk of cancer and thus might benefit from follow-up or further investigations. Recent developments in genomics have provided the technology, which enables screening for susceptibility or genetic defects indicating increased risk of cancer. In general, however,

according to current knowledge, only 5–10% of the cancers seem to be inherited – resulting directly from gene defects (called *mutations*) inherited from a parent. Thus due to most cancers being multifactorial in their origin, genetic screening is rarely cost-effective except in certain subpopulations (e.g., families) with increased risk for certain forms of cancer, for example, certain familial breast cancer mutations (e.g., BRCA1 & 2). This kind of genetic screening is based on the assumption that knowledge of risk enables either primary prevention via lifestyle, environmental changes, or via targeted medical interventions.

Screening Programs as Policies

The fact that even countries with rather similar cancer prevalence rates and the same available international scientific research evidence on the effectiveness of cancer screening, have adopted very different screening programs, shows how much screening is a policy decision. Policy decisions are dependent on the best available research evidence but also on contextual issues such as resources, characteristics of the population, know-how of the practitioners and policymakers as well as priorities and values of citizens (Satterfield et al., 2009). Further, the cost of large-scale or high-technology screening exceeds the resources of most societies. For example, in developing countries, low-technology options such as visual inspection for cervical cancer have been found feasible and also effective.

Screening programs are optimal for frequent cancer types for which a cost-effective, affordable, acceptable, and accessible screening test is available to the majority of the population at risk. Estimates of premature deaths avoided by screening vary from 3 to 35%. Different screening programs target different populations such as age groups depending on the prevalence of cancer and other factors. Performance of the screening tests can be measured by sensitivity, specificity, positive and negative predictive values. Sensitivity refers to the probability that a person who has cancer gets a positive test result, whereas specificity is the likelihood that a person not having cancer receives a negative test result. The positive and negative predictive values are the proportions of positive and negative results that are true positive (i.e., cancer) and true negative results (i.e., no cancer). The positive predictive value, and also to some extent negative predictive value, are affected by the prevalence of the disease in the screened population. For a given sensitivity and specificity, the higher the prevalence, the higher the positive predictive value of screenings tests.

Examples of Cancer Screening Programs

An example of a cancer amenable to screening is breast cancer (the most common female cancer) (by mammography screening), and also cervical cancer (by Pap test screening). Screening programs in several countries are based on the evidence from randomized controlled studies showing that disease-specific mortality among women over the age of 50 years was reduced by up to one-third due to mammography screening every 2–3 years (Kerlikowske et al., 1995). Nevertheless, more recently, benefits and harms of mammography screening have been debated. The decline in mortality from breast cancer has been explained in terms of improved treatment approaches rather than the effects of screening; also, the effects of potential overdiagnosis and the psychosocial consequences of the screening process have been emphasized (Gøtzsche and Jørgensen, 2013). An independent reevaluation of the evidence on mammography screening concluded that the breast cancer mortality reduction is probably around 15% instead of close to 30% as previously estimated, and that the claimed overdiagnosis with its negative consequences happens to some extent (Marmot et al., 2013).

For cervical cancer screening effectiveness there has been less strictly controlled research but also less debate; this is probably since the available screening programs can identify precancerous changes, which can be treated and thus prevent cancer from occurring. Screening programs in different countries have targeted a range of age groups and used different screening intervals, but in general, it has been shown that Pap test screening has been able to significantly decrease cervical cancer mortality (Peirson et al., 2013). Research has also brought new screening methods in addition to Pap test screening. One example of these is screening for HPV, some forms of which seem to be related to cervical cancer. Developments in this area have led to launching vaccination programs with the aim of preventing cervical cancer. In developing countries with a lower level of available technology and resources, studies have shown feasibility and usefulness of visual inspection using acetic acid as a cervical cancer screening method (e.g., Ibrahim et al., 2012).

Prostate cancer among males is an example of cancer screening, which has been studied in well-controlled trials. The most common screening method has been the PSA blood test indicating an increased risk for prostate cancer. Nevertheless, there is no conclusive evidence that PSA screening results in a significant reduction in either disease specific or overall mortality; further, potential harms (e.g., overdiagnosis and overtreatment) may outweigh the (uncertain) benefits of screening (Hoffman, 2010; Lee et al., 2013). Prostate cancer occurs mostly in old age and invasive treatment can cause a significant decrease in quality of life and functioning.

An example for cancer screening programs for both genders, which is carried out in several countries is colorectal cancer screening. For colorectal cancer screening several clinical tests exist, but also a self-administered stool sample test (fecal occult blood test) is available. It is currently estimated that these screening programs have led to a reduction in colorectal cancer mortality by 23% (Hewitson et al., 2008).

In the future instead of cancer-specific screening programs, it might be possible to do whole body screening for multiple sites using imaging technologies and serum marker tests.

Social and Psychological Aspects of Cancer Screening

Determinants of Screening Provision and Uptake

In society, screening can be studied from the perspectives of society, health services offered, and of people taking part in screening, although in real life these levels are interdependent

and imbedded. Different cultural, health system, and resource factors and values at society and service level *determine the screening provided* (Table 1). *Uptake of screening* is affected by the social and cultural context, the way screening is organized, and by individual factors. The more initiative is left to the individual, the more important is the person's health motivation in determining the use of screening programs. Interventions using postal invitation, telephone reminders, general practitioners' invitation, and appointment instead of open invitation and self-sampling, have been shown to increase cancer screening participation (Camilloni et al., 2013; Ferroni et al., 2012). Examples of individual-level determinants are socioeconomic background, health behavior in general, beliefs, perceived risk, and health literacy, knowledge as well as experiences related to illnesses in general, and to cancer and screening (e.g., Aro et al., 1999).

Theoretical models used to study determinants of cancer screening uptake have mostly been based on cognitive expectancy value models predicting self-initiated participation. These models have only been partly successful at predicting screening behavior, which is probably due to the fact that in screening, the social and service contexts are essential, which are not included in many individual and cognitive models (e.g., concept of intention, excluding concern and emotions). Also, these models are often too general for different types of cancer screening. Theories on treatment adherence or coping with threat can offer alternatives, but also stages of change theories can be applied to adherence to repeated screening rounds, especially if the context factors are included in the model. Though not easily administered in large-scale screening programs, personalized risk communication for informed decision-making about taking screening tests seems to increase informed decision-making compared to more general information. In addition, knowledge and accuracy of risk perception might increase using personal risk communication; anxiety about screening, however, does not seem to be affected (Edwards et al., 2013). A step forward to a more multilevel framework to understand cancer screening uptake and the role of socioeconomic factors has been presented by von Wagner et al. (2011). In this article, the authors describe possible pathways by which life experiences related to socioeconomic status (stressors, illness experience, resources, education) might influence psychosocial factors (e.g., beliefs, confidence) playing a role in cancer screening participation.

Implications of Screening Provision and Uptake

Screening Provision

Screening provision can have both positive and negative implications. Positive implications at society level include increased awareness of cancer and health in general (Table 1). At service level, positive implications can include increased competences among the screening and health care staff. At the individual level, screening provision can increase health motivation. On the potential negative side, at society-level screening provision increases costs and can also increase medicalization of the health conditions targeted by screening programs. The service level faces increased diagnostic work and treatment, demand on staff capacity and resources in general. People *invited* to, or otherwise made aware of screening, might get worried about the screened condition.

Screening Uptake

Screening programs aim at high uptake rates, which would increase lives saved, a decrease in morbidity and improvement in quality of life of those taking part, preferably in a cost-effective way (Table 1). This would bring benefits to the society. However, since screening also detects cancers, which otherwise would never become clinical, or which would appear so late that they would not lead to death or increased morbidity (overdiagnosis and overtreatment), screening

Table 1 Screening in a society: examples of determinants and implications of screening provision and uptake on different levels of society

[a]Not applicable.

uptake can also bring (unnecessary) workload and costs for service providers as well as harms to the participants, although these can be estimated only at group level. Most of the individual-level implications are related to the screening process, which may include several rounds of assessments. Already invitation to screening may raise worry and a screening test may be inconvenient (e.g., painful or embarrassing to some) or bring other hazards. A *normal screening finding* normally brings relief, but the screening procedure with additional assessments can cause worry (Aro et al., 2000; Metsälä et al., 2012). For those with a *false positive* screening finding, worry, especially cancer-specific distress, and its behavioral indicators such as preoccupation with symptoms, decreased screening uptake but also increased use of health services, might last long past the reassuring diagnosis (Aro et al., 2000; Bond et al., 2013). Further, distress seems to increase with the level of invasiveness of the screening procedure (Bond et al., 2013). *A true positive diagnosis* of cancer due to screening may both prolong life and improve its quality. However, this impact cannot be evaluated individually but only at a group level. Finding and treating cancer, which would never have become clinical in a lifetime, is clearly a major adverse effect of screening. *A false negative* finding misleadingly reassures and delays diagnosis. *A true negative* finding is reassuring, assuming that screening has no adverse effects.

Theories guiding research on implications of the screening process and its findings should cover cognitive issues such as perceptions and illness beliefs, coping with health threat, health behaviors, and quality of life. Persons needing to go through further assessments in the screening process especially need targeted attention and accessible material to alleviate their concern. It is important to take into account health literacy in general and especially cancer literacy of the target group of screening and of all screening participants; in delivering cancer risk information new genomic knowledge and its implications for cancer prevention and monitoring need to be taken into account.

Challenges in Cancer Screening and Research on It

Cancer – A Growing Problem

Screening, however, is not the solution for cancer control. It is cost-effective only for certain age or risk groups, and mostly not globally feasible. Prevention would be better than screening for an already existing disease, but only part of the causal factors of cancer are understood. It is estimated that about one-third of cancer deaths are due to the five leading behavioral and dietary risks: high body mass index, low fruit and vegetable intake, lack of physical activity, tobacco use, and alcohol use. Examples of these lifestyle-related cancers linked to economic development are lung, breast, and colorectal cancers. Due to the aging population the number of cancer cases will increase in the future. Even if fewer people will die from cancer in the future due to improved treatment in the high resource countries, the situation might not be the same in low resource settings. By 2030, the global cancer burden is expected to nearly double, growing to 21.4 million cases and 13.2 million deaths; most of these cancer deaths will probably occur in low- and middle-income countries.

Cancer Screening

Health literacy and especially cancer literacy, risk perception and risk communication as well as informed consent of participants in large-scale screening programs pose major challenges since screening programs should deliver messages to very diverse target groups with little face-to-face contact. Growing evidence on screening effectiveness and rapid developments both of biomedicine and of screening technology, require regular updating of screening-related material, decisions, and guidelines. Development of decision aids for public health decision-making (e.g., Tso et al., 2011) might prove useful – as long as these respect the inclusive and ethical principles of public health decision-making (Satterfield et al., 2009; Tannahill, 2008). From the public health perspective, instead of individually based *informed consent*, one could talk about *informed contract* between rapidly developing science and society in developing and deciding of health policies (Nuffield Council on Bioethics, 2007). To realize this kind of informed contract, public debate and the empowerment of citizens to take part in developing screening policies can be supported by public discussion on values, ethics, and priorities in communities and societies. Modeling software provides one way of forecasting effects and impacts of screening where as experimental studies are not acceptable or feasible. People need knowledge and skills to control the cancer problem in their roles of societal level decision-makers, service providers, and as individual citizens.

Research

Comprehensive research on social and psychological aspects of cancer screening is best done using a multilevel approach so that both determinants and implications of screening provision and uptake, including the levels of society, service, and the individuals, are taken into account. A prospective design with nonscreened referents – most easily built in organized screening programs with planned schedules – enables more reliable measurement of predictive determinants of both uptake and consequences of screening. Theory-based research using context-specific measures, which are specific to the health condition screened in addition to standard measures or those measuring clinical morbidity levels, might provide more useful information in terms of developing tailored support and interventions for screening participants in different phases of the screening process.

Conclusion

Cancer screening programs as health policies belong to multidisciplinary and multisector actions, which need careful updating, planning, monitoring, and evaluation. Determinants and consequences of both screening provision and uptake can best be studied at multiple levels of society, service, and individual level.

Cannibalism

Shirley Lindenbaum, City University of New York, New York, NY, USA

This article is a revision of the previous edition article by D. Tuzin, volume 3, pp. 1452–1454, © 2001, Elsevier Ltd.

Abstract

Cannibalism has a long-established place in the chronicles of human history. Shifting representations of the cannibal tell a story of changing Western sensibilities. Difference and novelty, once appreciated, were displaced during the eighteenth century by the ranking of societies on a single evolutionary continuum. Cannibalism became the prime signifier of barbarism, an attitude that would harden during the nineteenth century in biology-based racism. Archaeological and genetic evidence of cannibalism in ancient European population, as well as more recent historical reports, provide an opportunity for critical reflection on the meaning the practice held for ourselves and for others.

The practice of cannibalism, the eating of one's own kind, has a long-established place in the chronicles of human history. Archaeologists find evidence of human cannibalism before the invention of metals, the building of the Egyptian pyramids, and the origins of agriculture. The ancient literature from Homer to Strabo and the Roman historians mentions anthropophagi living on the borders of the known world. In the fifth century, Herodotus said man-eating people were found among the Scythians in the environs of the Black Sea. The Crusades provided images of savages who preferred human flesh to that of nightingales stuffed with spices. The word cannibal, rather than the older word anthropophagus, is said to be a legacy of Columbus' encounter with man-eating Caribs of the Antilles in 1492.

The shifting representation of the cannibal provides a history of changing sensibilities. Ancient, medieval, and early modern sources described savage nations of anthropophagi in semihuman form, hybrids of animal and man. For medieval travel writers, the typical cannibal monster was the cynocephalus, the dog headed being who inspired the imagination of Marco Polo. Idolatry and cannibalism were not condoned, but the behaviors of distant and strange races in Asia and Africa presented no challenge to European values. Thirteenth- and fourteenth-century authors portrayed difference and novelty as positive qualities, a source of pleasure and delight, although cannibal behavior served also to satirize courtly and aristocratic culture. Montaigne's denunciation in 1577 of the cruelty displayed by Christians against one another during the religious wars in France is viewed as an early statement of cultural relativism. There was more barbarity, he thought, in eating a man alive than in eating him after he was dead, as was customary in other nations, and in the tortures of the rack for bodies full of feeling, or roasting a man bit by bit, as had occurred among his fellow citizens on the pretexts of piety and religion (Montaigne, 1581). The Renaissance image of the heroic cannibal adopted by Montaigne and the first missionaries in the New World reflected the aristocratic values of magnanimity and chivalry. Renaissance views also held cannibalism to be 'natural' because the four humors make human flesh tasty to humans who are made of the same stuff.

The earliest images of cannibalism for European eyes were provided by the illustrators of the de Bry's *Great Voyages* (1590–1634). For these seventeenth-century Protestant engravers cannibalism, although not considered acceptable, was viewed as a theological sin, a form of immoderate eating; the Tupinambas were thus judged to be pagans and savages for committing one or another of four kinds of gluttony (Bucher, 1981). This view would soon be challenged by the greed of the conquistadors and the excessive zeal of missionaries. Political and economic conditions in Europe provided the context for dwelling on images of gourmandizing excess. Poverty and unrest allowed Protestant and Republican authors to focus on the sins of appetite associated with unreformed religion, and morality plays depict monks and priests as gluttonous lechers. The Spanish were viewed as tyrants consuming other nations to satisfy their Babylonian, Roman Catholic, and absolutist ambitions (Healey, 2002). Debate over the Eucharist, fraught with cannibal associations since the earliest days of the Christian church, became a major point of polemical contest in Reformation Europe. Carried to the New World, the analogy between the sacrament and New World anthropophagy allowed Calvinists to compare Catholics to the Outeca, cannibals who ate their victims raw, an allusion to sanguinary sacrifice in the Catholic mass (Rawson, 1997).

In the context of increasing overseas trade, religious proselytization, and imperial expansion, some eighteenth-century authors began to explore the perverse attractiveness of the image of the cannibal to reflect on certain features of their own society (Cottom, 2001). The trope of the good and the bad cannibal (the noble and ignoble savage) reappeared and became transformed with French and British adventures in the Pacific, which settled on new images of seduction and transgression. In 1719, Defoe portrayed the cannibal as a nexus of ambiguous desire; Robinson Crusoe is attracted both to the idea of eating human flesh and to being eaten. The ambivalence of cannibal transgression reached its extreme in de Sade's 1797 novel, *Juliette*, whose characters gorge on wines, liqueurs, shit, semen, and bits of human flesh, his critique of colonial exploitation perhaps undone by his exploitation of cannibal eroticism.

During the eighteenth century, a significant change took place in the way the inhabitants of the new worlds came to be understood. Renaissance perceptions of difference had been

religious, rather than racial or national. The intruders were not described as Spaniards, Europeans, or whites, but as Christians, and the 'Indian' was not a savage of any particular type, but a naked pagan, to be converted. The shift from religiously framed difference entailed new models for constructing otherness, couched in a narrative of natural history. Humanitarian assessments of dissimilarity (as well as some negative judgments) were displaced by a more uniform, intolerant denigration of physical inferiority and moral fault. This decisive move in Enlightenment thinking, away from mythological, religious causes of social evolution to material causes, recast the history of mankind in a single continuum, with societies ranked higher and lower on the same scale. A discourse about social progress depended on the figures of the noble and ignoble savage, formulated in terms of the West and the Rest, and provided a language in which Western modernity first came to be defined (Hall, 1992). Cannibalism was to become the prime signifier of barbarism for a language of natural typification and essential difference that would harden in the biologically based negative racism of the nineteenth century.

The image of the noble savage had attained sociological status with Rousseau's account of simple, unsophisticated people living in a state of nature, unfettered by government, property, or social divisions. This state of paradise was discovered anew with French and British explorations in the Pacific. Bougainville said of Tahiti that he thought himself transported to the Garden of Eden. When Cook arrived in Tahiti in 1769, the same idyll of sexual paradise and ideas of innocence were repeated, and when he brought the Tahitian Omai to Europe in 1774, his tattoos fascinated London society, sparking a tattooing vogue among the English aristocracy.

By the end of the eighteenth century, however, as maritime exploration turned its focus to the scientific classification of animal and human species, and with the death and disappearance of the navigator Defresne, killed and eaten by the Maori, as well as the death of Cook in Hawaii in 1779, the image of the noble savage was no longer tenable. The stereotype of the noble savage always contained its mirror opposite, the ignoble savage. In the South Pacific, the dualism became gendered in the form of the beautiful, enticing siren, and the malicious, bestial cannibal, a distinction that would be extended to civilized, white, Polynesians and savage, black Melanesians (Boulay, 2001).

Savage cannibals were reported to be present in nineteenth-century New Zealand. Maori warriors were said to eat fallen enemies and to have massacred and consumed the passengers of the crew of the *Boyd* in 1806. Perhaps the best-known account of the hazards of seafaring was that of the crew of the *Essex*, the whaling ship rammed by a sperm whale in the Pacific in 1820, the event that inspired Melville's *Moby Dick*. The crew of 20 took to three small boats and were blown around the Pacific for 90 days, enduring thirst and hunger, succumbing finally to cannibalism. Only eight of them survived.

The construction of the stereotype of the ignoble savage took place on many fronts. Beginning in London in 1851 and ending in 1931 in Paris, international exhibitions proclaimed the superiority of Western civilization. Visitors to the Paris exhibition were invited to view the skulls of primitive men organized by the exhibit's director of anthropology, illustrating the ladder of races with whites at the top. One hundred 'kanaks' were imported from New Caledonia for the 1931 exhibition in the Bois de Boulogne. Newspapers ran stories about two sensational attractions: crocodiles and wild cannibals. The kanaks also were exhibited as cannibals and polygynists in German towns, although most of these Polynesians by then were practicing Catholics.

Nineteenth-century missionary literature, called on to explain the existence of savagery in divine creation, described a migration of the sons of Ham, starting from the banks of the Euphrates, passing through India, and coming to rest in Melanesia. Thus, one found among the blacks in Africa, Asia, and Oceania "loathsome vices … and cannibalism in all its hideous subtleties" (Boulay, 2001: pp. 104–109). Nineteenth-century romantic images of the heroic missionary becoming a meal for cannibals, perhaps to impress mission donors, continued well into the twentieth century, a chestnut still found in cartoons and the repertoire of comedians. The discovery of gold in Papua New Guinea extended the life of similar tales of personal encounters with savage cannibals.

Airbrushed out of these mythologies of heroic adventure are the complexities of interethnic encounter and sexual confrontation, as well as the more gruesome stories of conflict, violence, and dispossession. To justify political intervention at the end of the nineteenth century, the adventure literature had settled on the Fijian King Thakombau (for the English) and Chief Bourarate de Hienghene, the 'king' of New Caledonia (for the French) to represent the abominations of anthropophagy (Boulay, 2001). Famine-based cannibalism was reported during the Siege of Leningrad in the winter of 1941–42 and in southern China during the Cultural Revolution. Japanese soldiers testified to eating their own troops, enemy dead, and prisoners of war in New Guinea during World War II when their daily rations were insufficient.

Salacious accounts of cannibalism are now a staple for the popular press, providing a frisson of pleasure for audiences reading about fellow citizens said to be suffering from severe personality disorder or psychosis. Interest in cannibalism appears to have increased in recent years, even as the practice becomes less frequent.

This brief walk through the history of human cannibalism illustrates the ubiquity, geographic diversity, and changing perceptions of the practice. The topic has long provided a vehicle for historians, geographers, philosophers, theologians, and others to speak about the realities of their time. The eater of human flesh once provided a vehicle for theoretical debates among the philosophers of natural law, an encompassing form of scholarship that had influence in the worlds of politics and science from the sixteenth to the eighteenth centuries, before philosophy, history, science, and anthropology became separate disciplines. The sciences of natural law may have disappeared, but dimensions of the debates are still present in anthropological inquiry (Lindenbaum, 2004).

Natural Law

The cannibal is said to be one of the great forgotten figures in the history of philosophy (Avramescu, 2011: p. 2). Avramescu's cannibal is depicted as a scholarly creature, viewed from the

perspective of natural law, the content of which is set by nature, and thus having universal validity. This pre-Enlightenment cannibal enters the collective Western imagination as a central figure in a theater of lawless figures existing in a condition of natural anarchy, a generalized war of all against all, as a shaper of European moral, legal, and political thought. The discovery of man-eaters in the Caribbean and travelers' accounts of cannibalism, real and imaginary, raised new questions for natural law.

Did these people believe in God and what was their conception of divine nature? Did they have a form of government, and if so, was it monarchical? Did they have private property? And did they eat people? Finding no description of such savages in the literature of antiquity or in the Bible, natural philosophers began to question the relevance of these texts. Were cannibals in a state of nature merely representatives of that state, and thus essentially good, or lawless savages whose human nature must be restrained by a strong sovereign? The cannibal entered the history of philosophy on both sides, as a positive representative, governed by the laws of nature, acting from absolute necessity, and as a deviant from its laws, committing crimes against nature.

The implications of anthropophagy raised a serious challenge also to the Christian doctrine of resurrection and the question of identity. When a starving man ate another, in what body would the man eaten be resurrected? Had his flesh been converted into the man who ate him? Would his flesh be restored to him, or remain part of the cannibal? Some Christian apologists solved this problem by asserting that the personal identity of a rational being consisted of its interior sentiment and that spiritual bodies differed from their earthly counterparts. The resurrected body thus would be a body that differed from the natural one.

The New World practice of cannibalism, considered to be a monstrous crime, presented a problem for evangelization. Are these anthropophagi men or subhuman beings, incapable of receiving the Gospels? Even if their quality as human beings is admitted, cannibalism is incompatible with any religious belief. The opinions of the learned were divided. Some said that knowledge of God was diffused among all nations, including the most barbarous, who might be enlightened by knowledge of duties toward God, without which they would lack the strength to respect God's commandments.

Difficulties arose also over the concept of salvation in the case of shipwrecks and war, when the bodies of men fed fish or animals that were later eaten by humans, a consumption chain that might result in men feeding other men. The seventeenth-century sciences redefined the problem of resurrection as a scientific project. Aided by the microscope, the original solid particles and vessels were said to be the entire body, the rest but extraneous matter, the nucleus remaining unaffected, and no confusion of bodies would be possible.

The seventeenth-century decline in the doctrine of demonism (a belief that fallen angels had, of their own free will, chosen Satan as their ruler), as well as increasing doubts about travelers' tales, and questions about some aspects of natural law, coincides with the disappearance of the cannibal from learned philosophical discussion, along with a particular style of argument, values, and sensibilities. The marvels that once commanded the attention of philosophers and medical men during the sixteenth and early seventeenth centuries also fell out of favor. Protestant and Catholic clergy, aided by philosophers and naturalists, banished marvels and miracles from intellectual discussion. The passion and unprecedented diffusion of marvels seemed to have fallen into the wrong hands and were now considered potentially dangerous, threatening the monopoly of the power of wonder by princes and churches (Daston and Park, 1998: p. 362). The exit of cannibals and demons from philosophical thought accompanied a change in elite sensibilities. The anthropophagus (the older term) was once a central figure in an inverted world in which the absence of supreme power led to a state of chaos, characterized by the practice of cannibalism. Once also a protagonist in a political and moral philosophy that had addressed the nature of the social order, the anthropophagus is said to have been eclipsed by the State, the new agent of absolute cruelty (Avramescu, 2011: p. 262).

Anthropology

By the end of the nineteenth century, anthropology had emerged institutionally and conceptually from natural philosophy, retaining the observational and taxonomic practices of the earlier sciences for the study of human diversity. The anthropological study of human cannibalism now distinguishes between *endocannibalism*, the volitional eating of a person from within the group, and *exocannibalism*, eating someone from outside the group.

Endocannibalism, often in the form of funerary consumption, has been reported to be present in Papua New Guinea (Gillison, 1983; Glasse, 1967; Knauft, 2002; Lindenbaum, 2013; Whitfield et al., 2008) and Amazonia (Conklin, 2001). *Exocannibalism*, as an act of aggression, frequently in the context of warfare, has been documented for the Americas, the South Pacific, and Africa. The Maka of southeast Cameroon reported eating people from outside their kinship network before their subjugation by the Germans in 1905 (Geschiere, 1998), and more recently by soldiers in the Congo. In some cases in Papua New Guinea and Amazonia both in-group and out-group consumption took place.

A taxonomy of cannibalism now includes behaviors that shade into Western medical and dietary regimes. *Medicinal cannibalism*, the ingestion of human tissue, has been reported since the first century AD. Pliny the Elder said that drinking human blood was a cure for epilepsy. From the sixteenth to the eighteenth century, Europeans ingested human blood and tissue as a medicine or tonic. Human flesh, blood, heart, skull, and bone marrow was obtained from mummy shops, where the embalmed and dried bodies of people who ideally had met with sudden or violent death was considered to be a universal panacea by the Paracelsians, who in contrast to the Galenists, promoted the use of a variety of medicinal body substances. The present-day traffic in human organs, tissue grafts, and human cloning now provides an avenue for *technological cannibalism*. The use of cadaver-derived drugs from pituitary glands for the production of human growth hormones from the late 1960s to early 1980s, led to several hundred iatrogenic cases of Creutzfeldt–Jakob disease in the United States, Europe, and Japan.

Autocannibalism (*autophagy*) refers to the act of eating parts of oneself: hair, nail clippings, mucous, and excrement, but also instances in which individuals under torture and duress partake of their own living flesh, raw or cooked.

Placentophagy, in which the mother eats her newborn baby's placenta, became popular in the United States with the spread of the home-birth movement in the 1970s. Some home-birth vegetarians eat the placenta, which they view as unkilled meat. Just as the home-birth movement provided a niche for *placentophagy*, consuming the ashes of a loved one became feasible in the United States as professional services for the cremated body were no longer felt to be obligatory. *Bone ash cannibalism* has been reported also in South America among the Amahuaca and the Yanomami.

Sacrificial cannibalism, in which the victim is treated with solicitude and honor as a prelude to sacrifice to a god, followed by cannibalism, occurred in fifteenth century among the Aztecs in Mexico, and in nineteenth-century Fiji.

Innocent cannibalism is said to occur when a person is unaware that he or she is eating human flesh. In Greek legend Atreus punishes his brother Thyestes for seducing his wife by tricking him into eating his own children. The unwitting ingestion of human flesh is also a theme in popular entertainment. 'Sweeney Todd' is based on the case of a murderous barber and a baker, partners in crime, who dispose of bodies by baking them into pies. A farmer in 'Motel Hell' makes smoked meats from individuals he considers to be contributing undesirable elements to the gene pool.

Invisible cannibalism is reported in Papua New Guinea among the Ankave-Anga (Lemonnier, 2006). Cannibal beings in immaterial form are said to travel through the air or underground, transforming into their semihuman or animal appearance when they arrive at their destination.

As Tuzin (2001) observed, the inventory of cannibal practices varies not only according to motive and circumstance, but also the diversity is so great that it overwhelms the common feature of ingestion, and confounds efforts to understand the practice as a unitary phenomenon.

Cannibalism and Anthropological Theory

Recent anthropological accounts of cannibalism take us through a twentieth-century history of theory in the social and biological sciences. Cannibalism, like incest, aggression, and other phenomena of supposed universal import, is a productive concept for exploring theoretical propositions. In the late 1950s, the structuralist concerns of British anthropology led scholars to examine cannibalism in the context of relationships among social structure, sorcery, politics, and warfare. At the same time, the utilitarian aspects of functionalism seemed to suggest that human flesh was of some nutritional value (an observation made by Evans-Pritchard in 1937), and an ecological explanation might be applied to tropical peoples living in low-medium population densities where they exploited a diverse range of animal foods. A materialist explanation also was proposed for the ritual slaughter and consumption of war captives by the Aztecs in fifteenth-century Mexico during times of famine and shortage of animal protein. Human flesh was said to provide incentives for warriors and also to sustain the power of elites. The Aztec case provoked a heated debate about population levels and ecological conditions in the Valley of Mexico, as well as the bourgeois grounding of Western-oriented materialist explanations.

Anthropological interest in the practice during the 1980s followed, in part, from Arens (1979) provocative suggestion that institutionalized cannibalism never existed because centuries of reports were not based on reliable eyewitness evidence. In response, many anthropologists reevaluated their data, and more nuanced studies became available from Papua New Guinea, South America, Africa, and Fiji. Anthropologists now acknowledge that institutionalized cannibalism occurred in some places at some times. Noting the ethnocentricity of the criticism, some also called for reflection on our own horror of the practice and for the topic to be discussed in ways that avoided resort to denial or euphemism. Like their scholarly predecessors, twentieth-century anthropologists were challenged by the problem of the 'thinkability' of cannibalism. Levi-Strauss (1964) asserted that superficial reactions of dismay to reports of the 'barbarous' customs of native communities should be resisted, first by separating off its purely alimentary forms, because famine can force men to eat anything, and what remains can be termed positive, since they stem from a mystic, magic, or religious cause. In the context of a theoretical shift in the 1970s and 1980s toward matters of cultural belief, cosmology, and ritual, Sahlins insisted that cannibalism is also 'symbolic' even when it is 'real' and that the practical function of institutions is not adequate to explain their cultural structure. The search for cultural meaning resulted in rich descriptions of cannibal cosmologies, dramas, and rituals.

Refinements of natural selection theory in the 1960s and 1970s had encouraged evolutionary biologists to tackle what they viewed as the vile and unsavory behaviors in animals, which they depict as rape, slavery, infanticide, mate-desertion, and cannibalism (Mock, 1992). Shifting away from classical group selection (the idea that traits evolve for the good of the population or species), most biologists proposed that phenotypic traits, including behaviors, evolved because of the net benefit to the individual's inclusive fitness. One consequence was that sporadic reports of such 'unsavory' behaviors in animals could no longer be assumed to be pathological or aberrant. Even these behaviors might have evolved if they typically conferred reproductive advantages on their practitioners. Attention turned to such topics as the proximate cues underlying cannibalistic acts (in rodents), the genetic basis for cannibalism (in flour bugs), and how population and community structure might be affected by these dynamics. For evolutionary biology, as in the other sciences, cannibalism had become a more-or-less respectable topic of investigation.

Archaeologists, too, had begun to examine what they viewed as the darker side of humanity. During the 1980s, studies of violence, slavery, and cannibalism displaced an earlier focus on nationalism and gender. For some decades, archaeologists had examined human and animal bones in the American Southwest, debating whether these remains were the result of starvation cannibalism, war, or the execution of

witches. In the late 1990s, sensationalist reports of cannibalism among Ancestral Pueblo people were met with dismay by Native American communities, and the findings were discounted by some scholars who acknowledged violence but not cannibalism. In 2000, however, the discovery of a human coprolite among the disarticulated bones of seven individuals in the hearth of a pithouse at Cowboy Wash in southwestern Colorado provided confirmation of violence and cannibalism (Marlar et al., 2000). Analysis of the coprolite, as well as the residue on a cooking pot, revealed the presence of human myoglobin that could have resulted only from the cooking and consumption of human flesh. Scholars from a variety of disciplines later reexamined the contentious topic of social violence in the pre-Hispanic American Southwest and its possible association with cannibalism. A multidisciplinary group representing archaeology, ethnohistory, biological, and cultural anthropology concluded that violence had been associated with warfare and probably witchcraft and that anthropophagy had occurred in specific instances, associated with ritual, and not related to hunger (Nichols and Crown, 2008).

The turn toward representation in cultural anthropology in the late 1980s gave new life also to accounts of cannibalism as a colonizing trope and stratagem used by colonizers to justify their predatory behavior. Postcolonial studies proposed that the figure of the cannibal was created to facilitate the cultural cannibalism of colonialism, the projection of Western appetites onto the cultures they consumed. A common feature in the history of cannibal allegations was said to be the combination of its denial among ourselves and its attribution to those we wished to defame, conquer, and civilize. In an atmosphere of postcolonial guilt, denial of cannibalism was extended to denial on behalf of those we now wished to rehabilitate and acknowledge as our equals (Rawson, 1997). Cannibal denial and the debate it engendered diverted attention from a deeper analysis of collective ideas of prejudice. The assumption about the cannibal nature of others is one instance of broader attempts to discredit political rivals, unfriendly neighbors, and ethnic groups to which the accuser does not belong.

As Clifford Geertz (1995) observed, cultural anthropology draws the greater part of its vitality from the controversies that animate it. In the 1990s, the topic of cannibalism lured Obeyesekere and Sahlins into a high-profile debate concerning how we should understand non-Western cultures. Obeyesekere's (1992) reading of the logs and journals of Cook's Pacific voyages had led him to consider the way 'cannibalism' had been defined. The dialogues tapped dark fantasies, psychic structures shared by both the British and Hawaiians – "an anxiety that the Other is going to roast and eat us" (Obeyesekere, 1992: p. 635). The rhetoric about cannibalism, he said, revealed more about the relations between Europeans and Savages during early and late contact than as ethnographic statements about the nature of Savage anthropophagy (see also Sahlins, 2003). The debate settled on details of Captain Cook's death in the Hawaiian Islands in 1779. Obeyesekere (an Enlightenment universalist) proposed that the Hawaiians were pragmatic, calculating, and strategic rationalists, rather like ourselves, and their lives should be understood along psychological lines. Sahlins (a relativizing historicist) took the position that cultures exist within distinct schema, discontinuous with modern, bourgeois rationality, to be understood along French structuralist lines. In many ways, the debate seemed to revive earlier discussions about primitive mentality (Levy-Bruhl, 1923).

The echo of the structuralism of Levi-Strauss is present also in French and Spanish essays in which cannibalism was 'good to think.' Lemonnier's (1992) account of the homogeneity of forms of bodily aggression among different Anga groups led him to suggest historical and structural transformations of an older cultural system common to them all. Similarly, Vivieros de Castro (1992) proposed that the theme of divine cannibalism held by the Arawete of eastern Amazonia, central to their definition of the human condition, was part of a broader complex of Tupi-Guarani ritual anthropophagy. Tupinamba cannibalism had no privileged explication, but it was part of an interrelation of several explanatory levels.

The idea of the cannibal in the postmodern world has been emptied of the urbane irony present in Swift's 1729 satire, *A Modest Proposal*, in which he argued that the sale of small Irish children for human consumption would rescue the economy, prevent the children of the poor from being a burden to parents, put a stop to abortions, and make men as fond of their pregnant wives as they were of their mares in foal. Contemporary forms of 'immoderate eating' for profit and entertainment, in which people eat as much of a given food as possible in a set time, or consume beetles and other questionable substances, also have lost the moral and political resonance associated with earlier forms of transgressive consumption. No longer a sin of gluttony, or a platform for ridiculing bourgeois behavior, popular enactments of transgressive eating merely play with the borders of modern sensibilities. Verrips (1991) suggested that cannibal themes in recent movies, books, and music, and in foods named after body parts, provide substitutes and satisfaction for cannibalistic tendencies in societies where the Eucharist has lost its sway, substituting new forms of sublimation that harness the deep-seated desire of humans to eat their own kind.

The topic of cannibalism continues to lend itself to explanatory trends in the human sciences, as anthropologists acknowledge the dangers of framing cultural difference in historical terms, ignoring the extent to which social and cultural practices encountered in the present are themselves products of modern, social, political, cultural processes, and sensibilities. Knauft's 1985 ethnography of Gebusi social life in Papua New Guinea presented an array of all-night ceremonies, dramatic sorcery inquests, and divinations that had led to the execution of sorcery suspects and an extraordinarily high rate of homicide. Most of those executed were sorcerers, considered to be inhuman, and routinely were cooked and eaten, treated in the same manner as game animals of the forest. When Knauft returned in 1998 he found that fundamentalist Christianity, schools for children, and the marketing of garden produce had effected changes so great that indigenous rituals mostly were limited to remote villages. Sorcery beliefs still were present, but sorcery inquests were rare and cannibalism no longer occurred. The Gebusi had internalized aspects of Western subjectivity, Christian morality and conduct, emulating what they perceived to be a more modern style of life and in the

process, incorporating a modern sense of self and personhood (Knauft, 2002).

The Cannibal We Know Today

All the major positions on cannibalism discussed by theorists today were well represented by the eighteenth century (Cottom, 2001: p. 145): Expressions of doubt, the idea that aggressive cannibalism was an act intended to evoke terror, and the idea that cannibalism was a result of famine. The universality of cannibalism is also a recurrent theme. The philosophers' discussion of the cannibal as a subject of universal history preceded the notion of the cannibal within every human being, the judgment of a contributor to the *Encyclopedie* (1751–65) edited by Diderot. In the early eighteenth century, the distinction between exocannibalism and endocannibalism arose in the context of arguments assembled around the right to conquer; if anthropophagi eat only the flesh of people who died from natural causes, or who were killed by others in their midst, this was not a justification for attack. The notion that the conqueror was as savage as the savages, a proposition associated with cultural relativism, appears in Book 1 of the *Iliad*, in Plato's *Republic*, in Aristotle's *Politics*, and Montaigne's *Selected Essays*.

In the 1980s, following 50 years of theoretical engagement with the topic, and global theorizing about cannibal practices, however, anthropologists confessed to being notably uninformed about ideas and practices in specific cultural settings, eliciting a call (Brady, 1982) for philosophical house cleaning around the complexities of getting to know cannibals. The taxonomic impulse of nineteenth-century science, which produced a list of behaviors based on the common feature of ingestion, and categories emerging from our own culture and institutions, was not well suited to this task.

We began to know cannibals somewhat better when Western-educated Papua New Guineans visited their own communities and wrote about the practice. John Waiko (1970) interviewed elderly Binandere men in Northern Papua who recalled with pride their own participation in 'cannibalism, raiding, and the like.' Martin Buluna's discussion (1995) of cannibalism in the Milne Bay area provided detailed descriptions of the protocol associated with the treatment and consumption of victims, elaborate feasting and dancing.

In recent years, anthropologists have begun to speak with women and men who consumed loved ones, and in some cases the enemy dead, and to hear what they thought about the practice. Former cannibals in Amazonia and Papua New Guinea describe the legal rules about who may and may not eat the deceased person, the moral responsibilities of the living to one another and to the dead, as well as the fate of the body and the spirit of the deceased person. The myths and rituals enacted in mortuary ceremonies are said to convey sentiments of love, compassion, and grief. We are presented with a vast theater of bodily and spiritual practices that define the political and moral boundaries of social life, conjoining ideas about cannibalism, human identity, the destiny of the human spirit, the relations among people and communities, as well as between humans and animals, embedded in concepts, philosophies, and moral landscapes that once engaged the natural philosophers (Gillison, 1983; Glasse, 1963, 1967; Lemonnier, 1992; Lindenbaum, 2013; Whitfield et al., 2008). As the Wari told Beth Conklin (2001), cannibalism was not all about the eating.

Recent studies suggest another shift in contemporary sensibilities that may rescue the image of the cannibal consigned to the pathological margins of culture and to the behavior of others. Tim White (2001) has asserted that osteological and archaeological evidence provides convincing proof of prehistoric cannibalism among many different peoples, including many of our ancestors. Molecular geneticists working with an anthropologist and the Fore people in Papua New Guinea have come to the same conclusion. Evidence of selection at the human prion gene locus suggests that kurulike epidemics (the epidemic transmitted when the Fore consumed deceased kin who had died of kuru) is said to have occurred during the evolution of modern humans when cannibalism was thought to be widespread (Mead et al., 2003). Elderly Fore women known to have consumed deceased kin, but who had not developed the disease, were shown to have a distinct type of prion protein gene that had provided relative protection when they were exposed to the infectious prion. Global patterns of diversity in the same gene suggest that European populations show similar, but older, evidence of selection, resulting in survival advantage during episodes of cannibalism and prion-related epidemics in ancient human populations. White's proposition that we had all once been cannibals now seems less provocative than it did in 2001.

The alliance between contemporary anthropology and medicine could be said to occupy some of the space vacated by the departure of natural philosophy. The message that we too were cannibals can be used to reinvigorate the moral imagination, said to have been censored by the conventions and discourse of modern science. The figure of the cannibal, long used to establish difference and construct racial boundaries, can now be called on in projects to deconstruct them.

Capital: History of the Concept

Heinz D Kurz, University of Graz, Graz, Austria

Abstract

The article discusses various types of capital and their roles in the social sciences. The emphasis is first on the concept of capital in economics and especially in the form of produced means of production. When one speaks of capital in this way, the problem of explaining profits is close at hand. The surplus approach of the classical economists is compared with Marx's theory of exploitation, marginal productivity theory, and Schumpeter's to trace profits back to innovations. The article then turns briefly to other types of capital, in particular 'social', 'cultural', and 'symbolic' capital, as they were investigated in sociology, especially by Bourdieu.

The term 'capital' was used in Medieval Latin as an adjective, *capitalis* (from *caput*, head), modifying the word *pars*, to designate the principal sum of a money loan. The principal sum was contrasted with the 'usury', the payment made to the lender in addition to the return of the sum lent, later called interest. This usage had become common by the thirteenth century and possibly can be traced back to the eleventh century in the first chartered towns of Europe (see Fetter, 1937). Later capital also represented, for example, a set of produced means of production, a fund invested in liquid assets, or human skills, so-called human capital. Here we focus attention first on capital as a factor of production, that is, instruments (plant and equipment, tools, machinery) and objects (raw materials, semifinished products) of production and skilled labor. Capital is a factor that can be accumulated, whereas other factors such as land and simple labor cannot. Earlier authors reckoned the means of subsistence ('bread') enabling workers to perform their tasks among the necessary inputs and thus capital. To the extent to which natural resources, such as land, have first to be brought into a form that can be used productively, the investment in these resources and the resources themselves get confounded; Karl Marx (1818–83) spoke of 'la terre-capital'. Productive capital yields its proprietor profits, a money loan yields interest, and land yields a rent. The explanation of the origins of the different types of property incomes and the determination of their levels was and still is one of the most controversial areas in economics.

In authors such as David Hume (1711–76) durable instruments of production were typically called 'stocks', a word also used to describe stores of tradable commodities and sums of money. With the inception of systematic economic analysis at the time of the physiocrats in France and the classical economists in Britain in the eighteenth century the term 'capital' gradually gained wider acceptance and was used alongside with such terms as 'stocks', 'funds', or 'advances'. François Quesnay (1694–1774) distinguished between three kinds of advances (*avances*) or capital goods, depending on their durability: yearly (raw materials, means of subsistence); long lived, i.e., surviving more then one yearly cycle of production (animals, tools); and very durable (melioration of land, investments in infrastructure). In *The Wealth of Nations* (1776) of Adam Smith (1723–90), we encounter the distinction between *circulating* capital and *fixed* capital. The former refers to capital goods advanced at the beginning of the period of production that contribute exclusively to the period's output: they 'disappear' from the scene at the same time as their value is transferred to the product. Fixed capital instead refers to capital goods that are long lived and cannot be traced on a given unit of output. In their case the idea of a material-cum-value transmigration into the product loses much of its appeal. Smith calls the former circulating, because it changes hands from producer to buyer, whereas the aged fixed capital item typically (but not necessarily) remains with the producer. David Ricardo (1772–1823), a most successful stock jobber at the London Exchange and thus familiar with annuities, in his *Principles of Political Economy and Taxation* (1817) put forward a theory of value that also covered the problem of the wear and tear of durable instruments of production and their depreciation over time. Interestingly, he and other classical authors put forward the idea that a coherent treatment of fixed capital presupposes a joint-products framework: a fixed capital item that enters production at the beginning of the production period is considered as a different commodity from the item that exits at its end as a by-product of the main product (think, e.g., of a tractor used in the production of wheat). In this way fixed capital can be reduced to circulating capital. John von Neumann (1903–57) and Piero Sraffa (1898–1983) analyzed the problem within such a framework.

In Marx's *Das Kapital* (1867) we find the distinction between *constant* and *variable capital*: the former refers to raw materials, tools, and instruments of production and represents 'dead' or 'saved-up' labor incorporated in the things mentioned, the latter refers to wage goods spent in employing living labor, which, according to Marx, is the sole creator of value. Profits in this view reflect 'unpaid labor' and thus the 'exploitation' of workers. This fact is concealed by the seeming equality of people in markets, where both sides agree to enter a contract. However, propertyless workers, who essentially own only their capacity to work, are forced to do so in order to make a living for themselves and their families. Their bargaining power is weak and therefore they have to accept long working days, low wages, and bad working conditions. Capital is to Marx essentially an asymmetric power relationship between the class of workers and that of capitalists. Labor saving technical progress, engendered by the capitalist competitive process, generates and continually refills an 'industrial reserve army of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03068-3

the unemployed', which perpetuates the weak position of workers in the struggle over the distribution of income. However, by progressively replacing living labor by dead labor (machines, etc.), self-seeking capitalists unconsciously destroy the source from which profits flow: the general rate of profits is bound to fall and with it capitalism. Marx puts forward a particular version of an invisible hand argument, as it had been developed at the time of the Scottish Enlightenment, with Smith as one of its towering figures: the unintended consequences of human actions, which may run counter to the interests of the agents.

The view that profits are the result of exploitation was challenged toward the end of the nineteenth century by the so-called marginalist authors (the concept of 'marginal productivity' had, however, already been developed by the German economist Johann Heinrich von Thünen (1783–1850)). The American economist John Bates Clark (1847–1938) and the Austrian economist Eugen von Böhm-Bawerk (1851–1914) were among the severest critics of Marx. Clark distinguished between *capital* and *capital goods*, the former being a fund of value earning its owner a return, which equals the 'marginal productivity of capital'. By this is meant the increase in output due to an infinitesimally small increase in the amount of capital employed, given the employment of all other factors of production. Profits thus reflect the relative scarcity of capital in production; they are the higher the more scarce capital is.

Böhm-Bawerk did not agree with Clark's explanation, but argued that profits (or rather interest, as he preferred to call them) are rooted essentially in two 'grounds': (1) Man exhibits a positive time preference in consumption, that is, prefers a given bundle of goods today to the same bundle tomorrow, etc. (2) More 'roundabout ways of production' are superior. To provide a well-known example of more roundabout processes: catching fish with bare hands is not very productive; jousting them with a spear is more productive; using a net and a boat is even more productive, etc. Through producing intermediate products (spear, boat, net) and then equipping workers with them labor productivity is increased. To produce first such intermediate products, that is capital goods, and not immediately consumption goods, presupposes some saving and investment. The first ground however says that people are not inclined to wait to consume, that is to save. They do so only, if they are offered an interest rate that exceeds their rate of time preference. The superiority of more roundabout processes of production allows for such an *agio*, which is interest. Since workers equipped with (more) capital goods exhibit a higher labor productivity than workers without, they have to share the increase in output with capitalists, who saved and invested and thus were able to endow them with capital goods.

As these examples already show, a main issue in capital theory is whether capital is 'productive' in the sense that it explains the existence of *profits*. Critical reviews of early profit theories are contained in Marx (1905–1910[1954]) and Böhm-Bawerk (1884[1890]). At the cost of severe simplification, the various traditions in the theory of capital and profits may be divided in two principal groups, one rooted in the surplus approach of the classical economists, the other in the demand and supply approach of the marginalist authors. Both traditions developed their arguments essentially within an analytical framework that presupposes competitive conditions and focuses attention on fully adjusted positions of the economic system, characterized by a uniform rate of profits and the corresponding set of normal prices.

The classical authors from Smith to Ricardo explained profits in terms of the *surplus product* left after the means of production used up in the course of producing given levels of output and the means of subsistence in the support of workers had been deducted from these outputs. Taking real wages as given is thus a characteristic feature of the early classical economists' approach (the level of wages was then discussed in another part of the theory, typically by taking into account, in particular, whether the society was 'improving', stagnant, or declining and whether the demand for 'hands' tended to grow more quickly than the workforce). Production was conceived of as a *circular flow* involving a strong degree of interconnectivity of the different industries of the economy. The rate of profits, expressed in material terms, is the ratio between the social surplus and social capital, i.e., two aggregates of heterogeneous commodities. A comparison of these two bundles of commodities necessitated the development of a theory of value. The classical economists tried to tackle this problem typically by first identifying an 'ultimate measure of value', which was designed to render heterogeneous commodities homogeneous. Several authors, including Ricardo and Marx, then reached the conclusion that 'labor' was the sought standard and therefore advocated some version of the labor theory of value. According to it the values of commodities are regulated by the amounts of labor needed directly and indirectly in their production. By means of this theory Marx in particular, in a first step, determined the rate of profits by assessing the labor values of the surplus product and the social capital. In a second step he then applied this rate to the capitals employed in the different lines of production in order to determine normal competitive prices, or prices of production. Ladislaus von Bortkiewicz (1868–1938) aptly called this approach 'successivist'.

Yet, as Sraffa (1898–1983) showed (Sraffa, 1960: p. 6), the successivist approach cannot generally be sustained: "the distribution of the surplus must be determined through the same mechanism and at the same time as are the prices of commodities", that is, simultaneously. The classical authors did not have at their disposal the instrument of simultaneous equations and the mathematics needed to solve them. This helps to explain why they had recourse to the labor theory of value. This landed them, in the case of Marx, in the (in)famous problem of the 'transformation' of labor values in prices of production. Commodities were produced by means of commodities and there was no way to circumnavigate simultaneous equations. Sraffa showed that a coherent formulation of the classical approach that was quite independent of the labor theory of value was possible: The rate of profits and competitive prices could be determined consistently in terms of the givens of the problem under consideration: (1) the system of production in use, characterized by the dominant methods of production employed to produce given gross outputs; and (2) the ruling real wage rate(s) (or the share of wages).

We may illustrate this in terms of the following numerical example with only two commodities, a and b. Assume that 30 units of a are produced by means of 10 units of itself and 12 units of commodity b, where the input quantities cover both

means of production and means of subsistence in the support of workers. We may write this in the following way: $(10a, 12b) \rightarrow 30a$, where $\rightarrow$ means 'produce'. Similarly, 20 units of b are produced by means of 8 units of a and 4 units of itself: $(8a, 4b) \rightarrow 20b$. The economic system as a whole apparently produces more than it uses up (or 'destroys') productively: $30a > 10a + 8a = 18a$ and $20b > 12b + 4b = 16b$. The system produces a *surplus* or *net product* of $12a$ and $4b$. In conditions of free competition this surplus product is distributed in terms of a uniform *general* rate of profits, r, on the *value* of the capitals employed in the two industries. This gives rise to the following normal price equations, where p_a designates the price of one unit of commodity a and p_b the price of one unit of commodity b:

$$(1 + r)\,(10p_a + 12p_b) \;=\; 30p_a$$

$$(1 + r)\,(8p_a + 4p_b) \;=\; 20p_b$$

If we measure all value magnitudes in terms of, say, commodity a, then this is equivalent to setting the price of commodity a equal to unity: $p_a = 1$. The two equations above thus have only two unknowns, r and p_b (the price of commodity b expressed in terms of commodity a) and can be solved. We get:

$$r \approx 0.4876 \;\text{ and }\; p_b \approx 0.847$$

In the numerical example given the rate of profits is just under 49% and one unit of b is worth about 0.85 units of commodity a.

The alternative marginalist explanation, which we have already encountered above, traces profits back to the productivity enhancing effect of the use of capital goods. It consists essentially of a generalization of the principle of intensive diminishing returns in agriculture indiscriminately to all industries and all factors of production alike. The older marginalist authors, with the exception of Léon Walras (1834–1910), were aware of the fact that in order to be consistent with the concept of a long-period equilibrium, the capital equipment of the economy could not be conceived as a set of arbitrarily given physical quantities of heterogeneous capital goods, but had to be expressed as a *value* magnitude: its commodity composition was seen to be a part and parcel of the equilibrium solution, determined by (1) preferences, (2) the technical alternatives from which cost minimizing producers can choose, and (3) initial endowments of the economy of labor, land, and *value capital*. The formidable problem for the marginalist approach consisted in the necessity of establishing the concept of a 'quantity of capital', which could be expressed independently of the 'price of its service', the rate of profits, and whose relative scarcity then determined that rate. If such a concept could be shown to exist, profits could be explained analogously to intensive rent on homogeneous land and a theoretical edifice could be erected on the universal applicability of the principle of the relative scarcity of a factor of production, which is the marginal productivity principle.

However, doubts as to the sustainability of this concept had already surfaced at an early time, especially in Knut Wicksell (1851–1926). Wicksell understood that a collection of heterogeneous capital goods can only be expressed as a single magnitude by using prices to render the various capital goods commensurable. However, as the equations above show, prices cannot be ascertained independently of the general rate of profits. The concept of a given 'quantity of capital', whose relative scarcity is taken to hold the key to an explanation and determination of the rate of profits, therefore presupposes already the knowledge of this rate. This implies arguing in a circle. This finding had prompted some authors such as John R. Hicks (1904–89) in the late 1920s and early 1930s to abandon the long-period method and adopt instead temporary and intertemporal equilibrium methods (Garegnani, 1976). Yet it was only during the so-called Cambridge controversies in the theory of capital in the 1960s and 1970s that the marginalist concept of capital was conclusively shown to be untenable in general (see Garegnani, 1970; Kurz and Salvadori, 1995: Chapter 14). It is based, among other things, on the idea that the methods of production can be ordered according to the amount of capital per unit of labor employed. Cost minimizing producers will then adopt from the set of alternative methods that one, which at a given wage rate maximizes the rate of return on capital. The higher (lower) the wage rate the more (less) capital intensive the method chosen, because producers have an incentive to substitute more expensive factors of production by less expensive ones: labor (capital) will be replaced by capital (labor). Yet Sraffa (1960) showed that this view cannot generally be sustained: methods of production cannot be ordered monotonically according to capital intensity or roundaboutness (Böhm-Bawerk).

The marginalist view applies only in exceedingly special cases, and it is ironic to see that these are precisely those in which the labor theory of value holds. Despite these findings, the concept is still widely employed, in much of macroeconomic theory, for example, with its reliance on 'aggregate production functions'. In more recent times also temporary and intertemporal models have been criticized from the point of view of capital theory; see the contributions by Garegnani and Bertram Schefold in Kurz (2000).

Joseph Alois Schumpeter broke with basically all previous analyses of capital and capitalism, but praised Marx for his deep insights into the *endogenous* dynamism of the capitalist system. He conceived of economic development as processes of transition between states of 'circular flows', that is, stationary economic conditions, triggered by 'new combinations', that is, innovations. He insisted that in the circular flow there are neither entrepreneurs nor capital nor profits nor interest. There are only static firms and the only incomes paid are wages of labor and rents of land. It is the entrepreneur who awakens the system from its slumber in terms of new goods, new methods of production, new forms of organization, new markets for his products and raw materials, etc. The innovator typically enters the scene without the means to realize his projects. He needs credit, which he gets from the banker, who creates additional money. Credit is the lever of a withdrawal of resources on behalf of the innovator. In an economy in which all productive resources are fully employed, an increase in the overall demand in monetary terms leads to an increase in the prices of productive resources. The inflation induced by credit expansion can be compared to a tax on static firms and channels into the hands of the entrepreneur the resources he needs. It is only with credit that 'capital', 'profits', and 'interest' enter the stage. According to Schumpeter capital consists exclusively of the

purchasing power handed over to innovators. It is not itself productive, but a precondition to be met in order for productivity increases to obtain. Neither produced means of production nor accumulated savings are capital, as received theory contends, capital is rather credit given to new producers. Schumpeter therefore speaks of his "purchasing power theory of capital" (1912: p. 255). Capital, profits, and interest exist only in a dynamic economy, not in the circular flow – a view with which he challenged basically all existing theories, classical, Marxist, marginalist (neoclassical), or Austrian. Both Böhm-Bawerk and decades later Schumpeter's student Paul Anthony Samuelson rejected this view.

With the process of globalization going on, there is a tendency toward an internationalization of capital and the worldwide equalization of the rate of profits on capital. An analysis of the factors affecting this rate is an important task in contemporary economic analysis.

From an early time onward, economists and social scientists in general drew the attention to the role of institutions, norms, customs, and habits for the quality of life and the performance of socioeconomic systems. Smith, for example, insisted: "Commerce and manufactures … can seldom flourish in any state in which there is not a certain degree of confidence in the justice of government" (WN V.iii.7). Justice, fairness, and the absence of corruption were seen to engender trust among individuals, thereby reducing transaction costs and increasing productivity. Early soundings of the more recent concept of 'social capital' referring to social cohesion and interconnectedness can be found in writers such as James Madison, a coauthor of *The Federalist Papers*, and Alexis de Toqueville in his study of the American democracy.

In more recent times the concept of social capital was developed to encompass all the benefits, economic and other, derived from the quality of relationships and forms of cooperation between individuals and groups. The concept became particularly prominent in sociology with the contributions of Pierre Bourdieu (1930–2002), especially Bourdieu (1984), who also introduced other categories of capital into the analysis, especially 'cultural capital' and 'symbolic capital'. Bourdieu defines social capital as the amount of resources controlled by an individual or a group as a consequence of it being a part of a network of more or less institutionalized relationships of mutual acquaintance and recognition. The social capital of an individual (or a group) reflected in its social positioning gives it access to resources above and beyond its economic capital. Each individual is seen to be describable in terms of the amounts of the various kinds of capital at its disposal and the networks it belongs to; a description in terms of social class membership is not good enough. The distribution of the various kinds of capital among individuals (and groups) is the key to power relations in social life shaping the latter's dynamics. Bourdieu shows how the complex of social relations and the activation of each individual's array of capitals in everyday practice are able to engender or reproduce inequality. In Bourdieu's view 'symbolic capital' is a particularly important source of power, because it is typically not perceived as such. By activating their symbolic capital (prestige, honor, etc.) – in the extreme as 'symbolic violence' – its holders exert an influence on the thinking, perception, and action of dominated agents who are inculcated with a belief in the legitimacy of the going social order. Bourdieu succeeds in showing how the ruling classes manage to preserve their social position across time, a fact that stands in striking contrast to the view that postindustrial societies are characterized by a high degree of social mobility, equal opportunities of its members, and the like.

The concept of social capital was further developed and popularized by Robert Putnam's *Bowling Alone* (2000). In economics it implies parting company with the analytical workhorse of much of modern economic analysis: the *homo oeconomicus*. The World Bank in the late 1990s initiated a research project designed to assess the value added gained by taking the concept of social capital into account in economic analysis and policy.

Abstarct

The term, capitalism appeared in the mid-nineteenth century. It has various interpretations, Marxist and post-Marxist, as well as anti-Marxist concepts. Chronologically one may differentiate among merchant, industrial, and financialized globalized capitalism. In the interwar decades, alternative regimes – Fascist and Communist economic systems – emerged. After World War II consumer and welfare capitalism were introduced. In the history of capitalism regulated and laissez-faire system rotated. In the late twentieth century, an Asian model and state capitalism became especially successful in emerging market systems.

Capitalism is an economic system based on free markets, credit creation, private enterprise, and ownership. The term and concept of capitalism as an exploitative socioeconomic system was initially introduced by Marxist social sciences. The spread of the term, however, was strengthened and its concept changed by the Western critiques of Marxism and socialism. Although rarely used, sociology and economics accepted the term and historiography broadly discusses its half-a-millennium development and various stages from commercial to globalized capitalism. The term was rarely used in the Western world during the Cold War ideological confrontation of East and West, but reappeared again, especially after the 2008 financial crisis.

Concepts and Theories

The term, derived from *capital* (root in Latin *caput*, 'head') and related to *capitalist*, appeared in the mid-late nineteenth century in the English, German, French, and other European languages. The word *capital* had been used from the seventeenth century onward in the economic sense, meaning 'fund of money,' and later 'principal' (as opposed to *interest*). The term *capitalist* appeared in mid-late eighteenth century French, English, and American texts. The first recorded occurrence of the form *capitalism* in English is 'The sense of capitalism sobered and dignified Paul de Florac' in Thackeray's *The Newcomes* II (1854). The spread of the term *capitalism* in common language use paralleled its use in Marxist socioeconomic theory, the appearance of s*ocialist–communist* economies in various countries, and the expansion of Cold War rhetoric based on the opposition of the two socioeconomic systems. The term and concept of *capitalism* as a socioeconomic system was basically introduced by the first theorists of Marxist social sciences. Although rarely used, sociology and economics accepted the term and historiography broadly discussed the transition from feudalism to *capitalism*, and the various stages of capitalist development from its early commercial phase via industrial and financial *capitalism*, to its late twentieth-century characteristics. The capitalist world system is often discussed according to the pattern of advanced core and dependent, backward periphery. Development studies and economics analyze late twentieth-century globalization and the increased role of transnational companies in a more interrelated, but at the same time even more polarized capitalist world economic system.

Karl Marx, who often used the terms capital, capitalist, and capitalistic, did not use the term capitalism as a noun in such basic writings as the *Communist Manifesto* and *Das Kapital*. The term appeared only later in his correspondence on the development of Russian capitalism during the late 1870s. The concept finally gained scholarly interpretation and became widely used by Marxist theory and the socialist movement in the last third of the nineteenth century. The concept was broadly used in historiography and sociology, but much less frequently in non-Marxist economics, to describe a phase of history or a set of ideas and mentality. During the twentieth century, capitalism became a popular term, especially to contrast the private market system with socialism. Marxist theorists interpreted the term capitalism as a socioeconomic system, a 'mode of production,' in which 'capital is not a thing but a social production relation belonging to a definite historical formation of society' (Marx, 1952; Chap. 48, English trans.; first published in 1867). Capitalism is a class society basically consisting of two antagonistic classes: bourgeoisie and proletariat. The system historically came about through 'primitive accumulation,' the separation of peasantry from the means of production, and the creation of a free proletariat deprived of property, whose only saleable commodity was its labor power. The ruling class, the bourgeoisie, owns the means of production, buys the labor power, and controls all economic transactions and production processes. In the capitalistic reproduction process, capitalists who own the capital buy various types of commodities (raw material, machinery, labor power, etc.) for producing new commodities for sale. In this reproduction process money is transformed into commodities, then again into money (M–C–M). The capitalist, however, is motivated by making profit and wants to get more money back at the end of the reproduction process (M–C–M′). The source of profit is one of the commodities – the labor power, which creates a 'surplus value.' The value of the goods produced by the workers is higher than the value of the labor power bought for a wage, which covers the expenses of the reproduction of labor power (including the reproduction of the class itself). Capitalists expropriate this 'surplus,' thus exploiting the proletariat. In capitalism, therefore, social production is in sharp contrast with individual expropriation. As a consequence, wealth is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62003-2

accumulated in the hands of capitalists, while the proletariat is kept in poverty. Capitalism, however, creates its own 'grave diggers' – the ever-increasing proletariat who, uniting together in the advanced West, rises up to destroy the capitalist system through a proletarian revolution. Bourgeois expropriators become expropriated and a just-communist society without classes and private ownership is established.

Post-Marxian Marxism revised this theory. Eduard Bernstein, the leading theorist of the powerful German Social Democratic Party, rejected the concept of proletarian revolution in his landmark article series, *Probleme des Socialismus* (1896). He argued that capitalism has developed in a direction different from the one indicated by Marx. Poverty has not grown but diminished, and welfare reforms have been accepted peacefully. Bernstein and the Western Social Democratic movement maintained that the proletariat could realize its interests and goals by organized mass movement and parliamentary reforms. Another leading German socialist, Rudolf Hilferding, in his *Das Finanzkapital* (1909), added that modern economy created 'consciously regulated social relations.' Later he concluded in the theory of 'organized capitalism,' thus, a state-controlled welfare system.

Revolutionary socialism emerging during the first decades of twentieth century redefined contemporary capitalism as the higher or the 'last' stage of capitalism, otherwise called *imperialism*. In her *The Accumulation of Capital*, Rosa Luxemburg (1951, English trans.; first published in 1913) maintained that C would not be able to expand its markets, recruit new labor force, and mobilize new resources without a 'third person,' i.e., noncapitalist (independent farmer) sectors of the advanced countries, and, most of all, the agricultural economy of the colonies and peripheries. The Russian Vladimir I. Lenin defined imperialism as a new, expansionist stage of capitalism, which was also characterized by the domination of 'monopolies,' where the competition of small individual capitalists is replaced by the deadly competition of monopolies, not only locally but also in the international arena. According to this view, capital exports became a new instrument for exploiting backward peripheral countries. Imperialism has led to the fight for the redistribution of the colonies and spheres of interest, and this unavoidably generates wars, and leads to the proletarian revolution of the backward world. This version of Marxism was the leading ideology of the Bolshevik Revolution in Russia, a revolutionary wave in Central and Eastern Europe after World War I, and the communist takeover in a series of Central and Eastern European, Asian, and African countries after World War II.

Non-Marxist scholarship did not build on the Marxist concept and interpretation of capitalism, but the term itself became commonly used in scholarship. Many twentieth-century sociologists and economists used the term capitalism to mean a society and economy based on free market and entrepreneurial interest, and accepted these characteristics as the essence of capitalism, in contrast to socialism. Critiques of Marxism, therefore, contributed just as much to the spread of the term and concept of capitalism. Because of his work on the role of Protestant ethic in the development of capitalism, Max Weber played an instrumental role in making capitalism a commonly used term in scholarship. Ludwig von Mises and his disciple Friedrich von Hayek frequently used the term capitalism when launching the most radical attacks against Marxist theory and socialist economy and defending an undisturbed free market. Joseph Schumpeter's book *Capitalism, Socialism, and Democracy* (1943) emphasized the changing evolutionary character of capitalism because of its entrepreneurial interest that 'incessantly revolutionarizes the economic structure from within' and with a 'creative destruction' destroys the old, outdated and creates the new. Joyce Appleby also characterizes capitalism as a 'relentless revolution' (2010), with a built-in ability of renewal.

The broadly accepted non-Marxist meaning of capitalism is rather different from the Marxist interpretation. According to the most widespread definition, capitalism is a complex socioeconomic system where the bulk of the means of production is in private hands guaranteed by modern property rights and laws. An 'invisible hand' (Adam Smith), the operation of market, regulates the entire economy, production, distribution, and labor. The market operates according to the play of supply and demand, which influence price fluctuations and automatically regulate investments and output. As the Say-law phrased it: each supply creates its demand. The market mechanism, therefore, is a self-regulating system. Capitalist entrepreneurs are acting individually and freely in a rational organization and control themselves with double entry bookkeeping, motivated by gain and increase of profit. Capitalism, in this sense, is in sharp contrast with both its rigidly regulated feudal predecessor and twentieth-century rival socialism. Hereditary, almost unchangeable social status, basically non-commercialized production for local consumption, strict communal and guild regulations, and the lack of free private property, labor, and market make economic relations in feudalism rigid opposed to capitalism; and nonmarket economy based on state ownership and central planning contrast socialism to capitalism. While capitalist society in its early stage has been, and in contemporary backward countries is characterized by extreme social polarization and income inequity, capitalism granted equal rights and, in principle, freedom of choice later in the advanced countries. From the 1870s on, but mostly from the 1950s, the industrial working class began shrinking, and the 'white-collar' layers, including the middle class, gradually expanded and became the most dominant layer of society. From the last third of the twentieth century, a two-thirds to three-quarters white-collar and middle class majority dominated advanced societies.

Early Stages of Development

Capitalism, broadly accepted as a phase of history, is dominating the last half-a-millennium. It has also become conventional that capitalism itself had various phases and stages. Its antecedents go back to ancient history. Barter and exchange of one thing for another, as Adam Smith, the main advocate and ideologue of market capitalism argued, are a part of human nature. The pockets of private market economy and its institutions, especially in urban settlements, flourished in medieval Europe. Joseph Schumpeter maintains that history of capitalism that goes back to the period when credit was created. Moneylenders and urban merchants, mostly in North Italy were its main representatives. Its continuous development,

however, began mostly from the sixteenth century. Historiography produced a vast literature on the transition from feudalism to capitalism. These writings maintain that declining productivity, a demographic crisis, and the scarcity of peasant labor generated the lowering of rents, a decrease of labor services, and an increase in peasant mobility and freedom in Western Europe. In most of these countries, consequently, serfdom was gradually loosened and disappeared by the sixteenth century. Commercialization of agriculture played a central role in the development of capitalism. The flourishing textile industry in Britain with an excess production over consumption led to the enlargement of productive capacities in an unheard scale and made England the 'workshop of the world.' This stage between the sixteenth and eighteenth centuries is often called 'commercial capitalism' in history. The system was based on private ownership of warehouses and ships and buying and selling goods all over the world. The merchants also lent out money at interest and established connections with production. They bought and distributed raw materials for peasants who worked at home in the traditional way (putting-out system), and gradually subordinated the rural cottage industry. It led to a proto-industrialization, the development of a decentralized putting-out system coordinated by merchants and later the establishment of (nonmechanized) factories, which introduced division of labor in the production procedure.

The emergence of capitalism, as various historians have discussed it, also gained incentive from the discovery of the 'New World.' The unlimited inflow of gold and silver from Latin America led to the accumulation of wealth. Although Spain was the main beneficiary at the beginning, most of the wealth got into the hands of Dutch and English merchants. "It is not the importation of gold and silver – stated Adam Smith – that the discovery of America has enriched Europe … [It] made a most essential [change] … by opening a new inexhaustible market to all the commodities of Europe, it gave occasion to a new division of labor." The new markets and emerging Atlantic trade enriched the commercial powers of Northwest Europe and made them the core of the emerging modern world system from the sixteenth century on. This period saw the rise of modern world trade, characterized by the trade of mass consumption goods of food and textile, instead of the medieval trade of luxury goods from the Near East and India. While the core countries of Western Europe sold processed industrial products, they bought unprocessed raw materials and agricultural produces from the peripheral countries of the world system: Latin America and Eastern Europe.

The rise of capitalism was strongly influenced by cultural-ideological and institutional factors. The Protestant reformation of the sixteenth century created a new work ethic and lifestyle, which was a prime mover of capitalist development. Hard work and thrift became virtues, which was in sharp contrast to parasitic noble values and lifestyle, the so-called *Hidalgo* (Spanish) and *Szlachta* (Polish) attitude. Meanwhile, the new moral code legitimized capitalist inequity: character was idealized, richness considered to be the triumph of will and work, poverty became a moral failing. In the absolute state between the sixteenth and eighteenth centuries, centralizing policy creating uniform monetary systems, legal codes, unified and defended home markets without internal tariffs, also played an important role. The isolation of the domestic market by limiting imports was accompanied by a tremendous effort to build up a large colonial empire and a system of various privileges and stimuli for exports. The *mercantilist* state itself became a promoter of the development of market, industry, trade, and transportation by the creation of road systems, canals, navies, and even state-owned industries. In the early modern centuries, important institutions such as modern property right were introduced that created a stable environment for rising capitalism. Meanwhile, in the most advanced countries in Northern Europe new consumption attitude emerged, the 'industrious revolution,' and a new scientific method, experiment and applied sciences, an 'industrial Enlightenment' gained ground. All these developments historically paved the way for dramatic capital accumulation, enlargement of markets, and technological experiments, new trends that led to the rise of modern capitalism.

Industrial Capitalism and Beyond

In the last quarter of the eighteenth century, Adam Smith published his powerful theory and ideology of the free market system, the *Wealth of Nations*, which became instrumental in the development of laissez-faire capitalism. Smith argued that from the selfish activity of the entrepreneurs, driven by profit motivation, the entire society profited, and that the individual actions, because of the self-regulating impact of the market, created an economic harmony and well-being for the nation. Smith established the economic thought and popular thinking on capitalist market economy for two centuries. Political thinkers and economist of latecomer countries, however, attacked British *laissez-faire* ideology. The American Hamilton and Germans Johann-Gottlieb Fichte and Friedrich List argued against *laissez-faire* in favor of protective state interventionism.

The end of the eighteenth century is considered to be a turning point in the development of capitalism. As a consequence of the British Industrial Revolution, anew stage of more mature, as social scientists and historians called it, 'industrial capitalism' emerged and dominated the nineteenth century. Starting in Britain, the industrialization process transformed the core countries of the capitalist world system into industrialized economies with a high, sustained economic growth. Industrial capitalism, in the first period of its existence, institutionalized long working days, and exploited female and child labor ruthlessly in the factory system. Living conditions of the workers in crowded and polluted industrial cities, as described by Charles Dickens and Friedrich Engels, were extremely poor. Capitalism, however, reached its dynamic period of development. A banking revolution in Belgium and France, then, most of all, in Germany, introduced the Credit Mobilér type, then the German type of investment banks with huge industrial portfolios. These banks played an instrumental role in industrialization. The relatively small, family-managed factories enlarged, and most of them became joint stock companies with professional management. From the mid-nineteenth century on, a European railroad system created a united European transportation network and an integrated marketplace. In this period virtually the entire globe became part of the capitalist world system. The core countries offered an unlimited market for food and raw materials. Britain and a handful of Western

European countries absorbed nearly 70% of the world's food and raw material exports. New institutions strengthened international capitalism, such as a free trade system and the gold standard – a fiscal underpinning of the free trade system making the national currencies convertible, which were gradually introduced from the 1860s and 1870s.

The expansion of capitalism around the turn of the nineteenth–twentieth centuries led to considerable changes in the system. Werner Sombart introduced the term of 'late capitalism,' and Rudolf Hilferding named this new period 'finance capitalism.' The concept of 'Imperialism' (Hobson) also appeared and became a leading concept of revolutionary Marxism. Some of the socialist theorists, however, such as Karl Kautsky, considered imperialism as a 'policy' of capitalism, similar to long workdays and child labor in its early phase. He maintained that capitalism could exist without colonies by introducing new policies. Twentieth-century capitalism was characterized by the challenge of major wars, worldwide economic depression, and a significant slowing down of economic growth. During World War I, the German war economy produced a 'war socialist' system that offered a more efficient regime even in peacetime. (Keynes) Alternative regimes such as fascist economic dirigisme emerged and challenged traditional capitalism. More importantly, capitalism had to face the challenge of socialism, first as a movement, then as a rival socioeconomic system. A great part of the twentieth century was characterized by the struggle of the two socioeconomic systems. Capitalism reacted by a highly flexible adjustment to the new challenges.

During the wars and depression, the development of state capitalism with a strong and effective state interventionism, a return to protectionism, inflationary financing, and even state investments and planning, helped the system to respond to the new challenge. Large state-owned sectors emerged in Italy, Spain, and Poland. National planning was introduced in Germany and Hungary to cope with economic decline and unemployment, and also preparing for war. Self-regulating, *laissez-faire* market capitalism was replaced everywhere by a regulated market system. Adam Smith's theory was replaced by John Maynard Keynes' concept of state interventionism to create additional demand.

The Welfare State, Mixed Economy, and Back to Globalized Laissez-Faire

The socialist challenge of capitalism required an effective response. The first chapter of this rivalry was opened in the late nineteenth century. Chancellor Otto von Bismarck, in his struggle with the strong German socialist movement, turned toward the introduction of welfare institutions. Pension system, health care, and other welfare institutions were introduced for workers to take the wind out from the sail of the emerging socialist movement. For these developments, the Great Depression of the early 1930s brought about a turning point. The Swedish Social Democratic government, elected in 1932, started building a welfare state. President Franklin D. Roosevelt also initiated major social legislation and the introduction of the social security system. The comprehensive system of the welfare state, however, emerged only after World War II in Western Europe. Capitalism, in contrast with its nineteenth-century features, initiated widespread social legislation. Paid vacation, short workweek, nationwide pension systems, free health care, education, maternity leave, cheap housing, and many other institutions were established. Citizen rights were reevaluated and the right to work, i.e., a full employment policy, became dominant. Inequity, at least in the middle layers of the society, markedly diminished in the advanced capitalist countries of Europe. The period after World War II also saw the spread of mixed economies. Almost all of the advanced Western European countries, led by France and Britain, nationalized entire sectors of their economies and established new state-owned firms in various industries. In some countries, such as France or Japan, even government planning was used to guide modernization of the economy. Capitalism underwent a spectacular transformation.

In his article on *The Instability of Capitalism* (1928), the leading Austrian-American economist, Joseph Schumpeter, prophesied the transformation of the system and the fading of the original meaning of capitalism. He maintained that capitalism is inherently stable and able to recover from great crises, but generates socio-intellectual effects discordant with its spirit and institutions. As a consequence, 'Capitalism is … in so obvious process of transformation into something else … [that] it will be merely matter of taste and terminology to call it Socialism or not.' After World War II, and also toward the end of the twentieth century, capitalism adjusted to the new historical situation and markedly transformed but preserved entrepreneurial interest, market flexibility, efficiency, competitiveness, and reached its highest prosperity and fastest growth rate ever. The Western core countries of the world system successfully adjusted to a new technological communication revolution and became the leader of new technologies and the rise of postindustrial society.

During the long period of postwar prosperity, a part of the former Asian and South European peripheries of the capitalist world system reached a higher than average growth and became an integrated and equal part of the core countries. After a long period of rivalry, capitalism emerged victorious while the parallel world system of centrally planned state socialism, which conquered one-third of the world and influenced an even greater part by its policy after World War II, collapsed in 1989–91. The former Soviet Bloc countries introduced radical market reforms, thus reestablishing capitalism. During the last third of the twentieth century, *laissez-faire* capitalism became the leading Western model again. Neo-liberal economics triumphed and challenged mixed economy and welfare state. Capitalism in late twentieth century reached a new stage in its history. The main trend of this new age is globalization. National boundaries and national economies rapidly lost their importance. Multinational or transnational companies penetrated previously independent economies. Foreign direct investment became instrumental all over the world, including the advanced core countries. Toward the end of the 1990s nearly one-third of American exports and two-thirds of imports were intrafirm deliveries. About one-third of French, Dutch, and British industrial output was produced and roughly 25–40% of their research and development expenditure was financed by affiliates of transnational companies. In Ireland, and former state-socialist Hungary, foreign affiliates produced

two-thirds of industrial output and financed roughly 70% of research and development expenditures. In several former Soviet Bloc countries the entire banking system was in the hands of Western banks.

From the late twentieth century, the advanced capitalist countries were deindustrialized and financialized. The financial and real estate sectors became larger than manufacturing. Capitalism became deregulated and high-risk 'casino' type gambling led to ballooning real estate bubbles in several countries. That period also became the rise of consumer-, or later even hyperconsumer societies. Government and household spending surpassed available incomes and led to extreme indebtedness of households and governments in several advanced countries, and former peripheral ones that virtually did catch-up and reached the advanced level. This trend led to the explosion of the 2007–08 liquidity crisis that generated a financial panic and recession in several countries. In Europe, the common currency of the European Union, the euro was also endangered. The Great Recession of the early twenty-first century led to a new wave of regulations in the United States and Europe, mostly coordinated by international organizations such as the G-20 organization of the economic powers.

While globalization, in some cases, contributed to a successful catching-up process with the core, it also preserved and even strengthened the core–periphery inequity. The gap between advanced core and the peripheries was growing considerably: intercountry income spread was 10:1 in 1913; 26:1 in 1950, but it increased to 40:1 at the end of the twentieth century. The so-called *Gini index* of inequality reflects broadening income disparities in the United States, and also in Europe. A newly globalized but even more polarized capitalist world system, dominated by an expanding Western core, was emerging at the turn of the millennium.

Globalization, however, had also positive influence for several Asian countries and an Asian model of modernization and capitalism emerged. After Japan and the small 'Asian Tigers,' China, India, Vietnam introduced an effective state-capitalist system and a strong export-led industrialization. Their unparalleled economic growth started transforming world capitalism and the global power relation.

Abstract

Capitalist globalization is defined as the phase of capitalism in which the transnational capitalist class (TCC) gradually takes a leading role in the global system. The TCC consists of four overlapping fractions, dominated by the corporate (those who own and/or control transnational corporations and their local affiliates). The analysis highlights economic, political, and culture–ideology issues. The crises of class polarization and ecological unsustainability, endemic to capitalist globalization, are discussed in the light of resistance to global capitalism and alternative forms of globalization, based on noncapitalist principles of social justice.

Introduction

While the idea of international capitalism has been part of political economy and related disciplines for more than a century, the concept of global capitalism (or capitalist globalization) is of more recent origin. Despite the fact that many scholars have used the terms interchangeably, one consequence of the popularity of the concept of globalization in the 1990s and the first decade of the new millennium was the increasing force of the argument for a firm distinction between the international and the global. International capitalism has generally been conceptualized in state-centrist terms, focused mainly on how national capitalists based in competing national economies and working through national companies operated across borders. The distinctive concept of global capitalism takes its departure from the idea of a global economy dominated by those who own and control globalizing corporations, and those who serve their interests. In the 1960s, a distinctive concept of global capitalism began to emerge from the transitional idea of capitalist world economy through several attempts to establish a genuinely global conception of capitalism not grounded in national economies and societies. In the years between then and now, periodic booms and recessions in various parts of the world have increasingly been analyzed in terms of the global capitalist system. The global financial crisis that came to a head in 2008 and spread throughout the world, with a few notable exceptions, is the latest in a long history of capitalist crises, recessions, and depressions. While global capitalism appears to have weathered the 2008 storm and has (so far) averted collapse at the systemic level, the severity of the crisis has been compared by many commentators to the great world depression of the 1930s. As in the 1930s, different regions of the world, different parts of countries, and even different neighborhoods in cities and towns have experienced the events of the last few years in very different ways, further confirmation of an increasing class polarization crisis in the era of capitalist globalization.

Researchers on global capitalism have focused on three interrelated phenomena, increasingly significant since the 1960s. These are, first, the ways in which transnational corporations (TNCs) have facilitated the globalization of capital and the production of goods and services (Sklair, 2002; Dicken, 2007); second, the rise of new global forms of organization of the capitalist class (Sklair, 2001; Carroll, 2010); and third, transformations in the global scope of TNCs that own and control the mass media, notably television channels, transnational advertising agencies, and the digital economy (Herman and McChesney, 1997; Fuchs & Mosco, 2012). Attention has been especially focused on the role of TNCs, large and not so large, in promoting global brand consumer goods and the emergence of a global culture and ideology of capitalist consumerism. Theory and research on each of these three phenomena roughly coincide with attention to the economic, political, and culture–ideology spheres of global capitalism. Resistance to capitalist globalization in theory and practice also revolves around these three areas of contention.

Global Capitalism as an Economic System

It is no coincidence that interest in a global capitalist system in contrast to competing national capitalisms has increased perceptibly since the 1960s. The context of theoretical and empirical interest in competing national capitalisms was (and for many still is) the history of colonialism and imperialism. This is overlaid with several versions of the theory that capitalist states could more or less successfully plan their own economic futures (see, for example, Keynesianism, regulation theory, and the developmental state). The concept of international capitalism, therefore, refers to a system of interacting and competing national capitalist economies, in which national elites of various types use 'their' big business (and businesses) to further 'their' national interests around the world. As direct imperialism and colonialism came to an end and as increasing numbers of very large TNCs began to emerge in the 1960s, attention began to shift decisively from national to global capitalism.

The dependency approach to development and underdevelopment of Gunder Frank and the related world-systems approach of Wallerstein both highlighted the systemic nature of capitalism as a worldwide phenomenon over several centuries. While these theoretical innovations can be said to have prepared the ground for it, neither entirely succeeded in establishing a coherent concept of global capitalism for what came to be termed the 'age of development' from the 1950s onward. This was due to ambivalence over their units of analysis and insufficient focus on the role of the major corporations in development in general. For example, the analysis of core, semiperiphery, and periphery in the world-systems approach is

based on national economies, as is the related concept of commodity chains. While both these approaches have generated large numbers of valuable studies on specific sets of economic exchanges and their productive and exploitative consequences (Babones and Chase-Dunn, 2012), the simple assertion that these take place within a world economy or global economy does not suffice for an analysis of global capitalism.

Theories of global capitalism, in the sense used here, take off from the proposition that capitalism entered a new, global phase in the second half of the twentieth century (Ross and Trachte, 1990; Robinson, 2004). By the end of the century, the largest TNCs had assets and annual sales far in excess of the gross national products of most of the countries in the world and this trend has persisted into the new millennium. In 2010, according to the World Bank, only 100 countries out of a total of around 200 for which there were even approximate numbers had gross domestic products (GDPs) of more than US$20 billion. By contrast, the Fortune Global 500 (FG500) list of the biggest corporations by turnover reported in 2011 that around 484 of them had annual sales greater than US$20 billion. This comparison, however, underestimates the economic scale of major corporations compared with sovereign states, as most TNC revenues are counted as part of the GDP of some countries. The largest economic entities in the world in terms of GDP are the United States, China, Japan, Germany, France, United Kingdom, Brazil, Italy, India, Canada, and the Russian Federation, all in excess of a trillion US dollars (the United States in 2010 was still the leader with a GDP of US$14.6 trillion, over twice the size of its two main (Asian) rivals). However, the top 50 corporations in the FG500, led by Walmart, the largest company in the world with US$420 billion, all had revenues in excess of US$100 billion. Therefore, in an important sense, such well-known names as Walmart, Shell, Exxon Mobil, BP, Toyota, Sony, Pepsico, Coca Cola, Apple, the huge Japanese trading houses, and many other corporations most people have never heard of like the Chinese state giants Sinopec and State Grid, have more economic power at their disposal than the majority of the countries in the world. These figures indicate the gigantism of TNCs relative to the economies of most countries.

Not only have TNCs grown enormously in size since the 1950s, but their global reach has expanded dramatically. Many TNCs regularly earn more than half their revenues outside the countries in which they are legally domiciled. This is the case not only for TNCs from countries with relatively small domestic markets (for example, Switzerland, Sweden, Canada, and Australia), but also for those legally domiciled in the United States and Japan. While most of the biggest corporations are still headquartered in what used to be termed the First World, around 100 companies originating in what was called the Third World or that part of it known as the newly industrializing countries have been numbered among the FG500 over the last few decades. This group has included the state-owned oil companies of Brazil, China, India, Mexico, Taiwan, and Venezuela (owned by the state but increasingly run like private corporations); banks in Brazil and China; and the Korean manufacturing and trading conglomerates (chaebol), some of which have attained global brand-name status (for example, Hyundai and Samsung).

Writers who are skeptical that capitalism is a global system argue that because most major TNCs are legally domiciled in the United States, Japan, and Europe, and because they trade and invest mainly between themselves, capitalism is still best analyzed in terms of national corporations. For such writers, the global economy is a myth and, consequently, there is no global capitalist system as such. Against this conclusion, theorists of the global capitalist system argue that an increasing number of corporations operating outside their countries of origin see themselves as developing global strategies of various types, as is obvious from the contents of their annual reports, other corporate publications and how they represent themselves in the mass media. While all parts of all economies are clearly not equally globalizing, an increasing volume of empirical research indicates that the production and marketing processes of most major industries are being de-territorialized from their countries of origin and that these processes are being driven by the TNCs. The central issue for economic globalization is the extent to which TNCs domiciled in the United States, Japan, and European and other countries can be more fruitfully conceptualized as expressing the national interest of their countries of origin (the globoskeptic argument) or expressing what can be conceptualized as the private interests of those who own and control them, aggregated as the interests of global capitalism. Even if historical patterns of TNC development have differed from country to country and region to region, it does not logically follow that TNCs and those who own and control them express any type of 'national' interest or national character. Industrial sector, for example, is often more important for explaining patterns of corporate operation than national origins.

The formal ownership of capital and the corporations has been transformed since the 1960s. The distribution of ownership of share capital has increased throughout the world by means of greater participation of the general population in stock markets and the indirect investments that hundreds of millions of people have through their pension funds and other forms of savings in the richer countries and for wealthy elites in less rich countries (although these people still constitute a small minority in most communities). The increase in the numbers of those actively involved in speculating in stock markets around the world has led some to argue that economic globalization has created a popular capitalism, although others argue the more elitist thesis that the real drivers of the global capitalist system are the managers of unit trusts and pension funds. Formal ownership, of course, does not necessarily mean effective control over capital and the resources of TNCs.

The focus of attention of those interested in generating a model of the future of global capitalist growth in the last quarter of the twentieth century was on the so-called newly industrializing countries (notably export-processing enclaves like Singapore, Hong Kong, South Korea, and Taiwan). However, in the opening decade of the twenty-first century, the focus switched to former member countries of the Third and Second (postcommunist) Worlds, heralding the rise of the BRICS (Brazil, Russia, India, China, and more recently South Africa) – all posting impressive economic growth performances while the traditional First World powerhouses of capitalism (North America, Western Europe, and Japan) languished in the throes of enormous government and private citizen debt, austerity policies, deep cuts in public investment, rising unemployment, low or negative economic growth, and financial crisis. It is too early to say, definitively, how robust

the BRICS model is, but the boosterism through which it is represented in the business media may be read as one indication of the increasing desperation of those charged with the management of global capitalism.

It is now commonplace to trace the present crisis of global capitalism to the financial crisis that broke in 2008. The globalization of the international financial and trading system can be fruitfully analyzed in terms of the progressive weakening of the nation-state, widespread deregulation, especially of financial markets, and the growing recognition that the major institutions of global capitalism, notably TNCs and globalizing financial and trading organizations, are setting the agenda for these weakened nation-states, not excluding the most powerful. The latest crisis of capitalism triggered by the global financial upheavals that saw the demise of some major institutions all over the world and the bailout by governments with taxpayers' money of others to avoid system meltdown has been vividly portrayed in the Oscar-winning documentary film 'Inside Job' (Ferguson, 2010). This can be understood within the context of what has been termed the culture–ideology of consumerism (C–I of C). The C–I of C is the consequence, on the cultural and ideological levels, of a crisis created by overproduction in the global capitalist system, made possible by the efficiency gains of the electronic revolution, and a chronic lack of real spending power – as opposed to borrowing via credit cards and bank loans – among consumers globally (Sklair, 2002). It is no coincidence that this latest and probably most severe crisis since the 1930s seems to have come to light due to problems with subprime mortgage lending in the United States, Europe, and elsewhere. Home ownership or its equivalent in secure leases is a central institution of capitalist globalization insofar as it stimulates ever-expanding demand for all the goods and services that keeps a capitalist economy growing. A bad situation – mortgage holders defaulting on their debts – was made significantly worse by the gradual disclosures that financial institutions all over the world had been speculating on these junk assets (derivatives). Thus, when the revenue streams from mortgage lending began to dry up due to foreclosures and home 'owners' walking away from their negative equity burdens, such financial instruments became worthless and once-revered financial institutions collapsed and some had to be bailed out by governments with tax-payers' money. The effects that this had on the 'real economy' (a term that the ideologues of capitalist globalization had successfully kept largely under wraps until now) are well known – banks are less willing to lend, businesses vulnerable to cash flow problems suffer, and jobs are lost. The only solutions on offer are platitudes that the economy needs to be stimulated, and governments become desperate to put cash in people's pockets to get them spending again while introducing ever more drastic austerity measures, debt increases, and so on. The general public is thrown into confusion and while criticisms of the irresponsibility of bankers and unregulated markets become a flood, especially in the context of a culture of huge bankers' bonuses, no alternatives to the so-called free market system are taken seriously by those charged with managing the global economy. Theory and research on this issue has, not surprisingly, led to an increased interest in the politics of global capitalism.

Global Capitalism as a Political System

The politics of global capitalism is debated intensely inside and outside the social sciences. Since the disintegration of the Soviet empire from the late 1980s, the struggle between capitalism and communism has been largely replaced by the struggle between the advocates of the neoliberal form of capitalist globalization and its opponents. Many theorists have discussed these issues within the triadic framework of states, TNCs, and international economic institutions. From this perspective, the global capitalist system is dominated by the relations between the major states and state systems (United States, North American Free Trade Agreement, the European Union, and Japan); the major corporations (FG500); and the World Bank, the International Monetary Fund, and the World Trade Organization (WTO) (supplemented in some versions by other international bodies, major regional institutions, and so on).

The idea of a transnational ruling class has been suggested by several theorists of the emergence of a global class structure in what was identified as the Gramscian turn in International Relations; for example, in the work of Gill (1990) on the Trilateral Commission, where he identifies a "developing transnational capitalist class fraction." Sklair (2001) proposes a more explicit concept of a transnational capitalist class, and it plays a central role in his theory of capitalist globalization. Here, the transnational capitalist class is the characteristic institutional form of transnational political practices in the global capitalist system (paralleling the role of TNCs in the economic sphere and consumerism in the culture–ideology sphere). In this formulation, the transnational capitalist class is analytically divided into four main fractions: (1) those who own and/or control major TNCs and their local affiliates (corporate fraction); (2) globalizing politicians and officials (political fraction); (3) globalizing professionals (technical fraction); and (4) merchants, media, and advertising (consumerist fraction).

A transnational capitalist class might be transnational in at least three senses. First, its members would tend to have outward-oriented global rather than inward-oriented national perspectives on a variety of issues; for example, support for free trade and neoliberal economic and social policies. Second, they would tend to be people from many countries, more and more of whom begin to consider themselves as citizens of the world as well as of their places of birth and residence (these might differ). And third, they would tend to share similar lifestyles, particularly patterns of higher education (in cosmopolitan business schools) and consumption of luxury goods and services. Theory and research to support this argument are as yet in a very embryonic phase. Nevertheless, and despite real geographical and business sector conflicts, the whole of the transnational capitalist class shares a fundamental interest in the continued accumulation of private profit on a global scale.

There exists a very wide variety of approaches to the politics of global capitalism. While Marxist, anti-Marxist, Marx-inspired scholars and those who have little interest in Marx mostly see capitalism as a global system, others tend to conceptualize globalization in much wider terms and minimize the importance of global capitalism as an explanatory variable (see the

collection edited by Lechner and Boli, 2011). Consequently, it is important to distinguish those approaches that assume that globalization simply means capitalist globalization from those that make distinctions between generic globalization, capitalist globalization, and alternative (usually noncapitalist) forms of globalization.

Global Capitalism as a Culture–ideology System

The third distinctive aspect of capitalism as a global system is the worldwide diffusion and increasingly concentrated ownership and control of the electronic mass media, particularly television (TV) and the Internet. In the last decades of the twentieth century, the number of TV sets per capita grew rapidly in developing countries (from fewer than 10 per 1000 population in 1970 to 145 per 1000 in 1995 (according to the United Nations Educational, Scientific, and Cultural Organization)) and growth has accelerated since then (it is estimated that there are now around 500 million TV sets in China). Ownership of personal computers also increased rapidly into the new millennium, ranging from over 800 per 1000 population in Switzerland and the United States to less than 2 per 10 000 in Rwanda. The average today appears to be around 60 per 1000 of the population, with the top 71 out of 168 countries having at least 100+ computers per 1000 of the population. Internet access has also penetrated deeply all over the world, even in towns and cities in very poor countries. By 2007, Greenland had almost total coverage (922 per thousand), the top 43 countries had 500 per thousand, and the top 134 countries had 100 per thousand (all data from www.nationmaster.com via Central Intelligence Agency Factbooks). Many researchers use such data to argue that a globalizing effect due to the mass media is taking place all over the world. Ownership and control of television, including satellite and cable systems, and associated media, including newspaper, magazine and book publishing, films, music distribution, and a wide variety of other, notably Internet-based, media are concentrated in relatively few very large TNCs. While the predominance of US-based corporations is being challenged by Japan-, Europe-, and Australia-based groups globally, and even by corporations like the Brazil-based media empire of TV Globo, there is wide consensus that – with few exceptions, notably Internet-based activity challenging the hegemony of global capitalism – the culture–ideology of consumerism drives all these media in the pursuit of private profit.

The culture–ideology of consumerism prioritizes the centrality of consumption and consumerism in contemporary capitalism – a system in which consumption expectations and aspirations are inexorably increased without necessarily ensuring the income to buy. The extent to which economic and environmental constraints on the private accumulation of capital undermine the global capitalist project in general and its culture–ideology of consumerism in particular is a central issue for theory and research on the capitalist global system. Nevertheless, most scholars studying these issues of global culture do so not in terms of capitalism per se but in terms of the potential impact of global culture on national and local cultures and identities, notably in the context of gender, ethnic, and lifestyle differences.

Crises of Global Capitalism

While Marxist and Marx-inspired theories of the inevitability of a fatal economic crisis of capitalism appear to have lost most of their adherents, at least two related but logically distinct contradictions of global capitalism have been identified. The first is the simultaneous creation of increasing poverty and increasing wealth within and between societies for rapidly expanding minorities all over the world, and increasing economic insecurity for the squeezed middle class (class polarization crisis). While Marx's emiseration thesis did not predict the enormous increases in the numbers of the very wealthy that have occurred in the last few decades even in some nominally poor societies, the relative position of the very poor all over the world appears to be worsening. The second contradiction of global capitalism is the unsustainability of the system in terms of environment and natural resources (ecological crisis). Globalizing corporations (in some cases rather more clearly than national governments) recognize the class polarization crisis, but largely in marketing terms. In most communities around the world the absolute numbers of people who are becoming global consumers have been increasing rapidly over recent decades. However, it is also true that in some communities the absolute numbers of the destitute and near-destitute are also increasing, sometimes alongside the new rich consumers. The best available empirical evidence comes from the United Nations Development Program annual Human Development Reports (undp.org/en/) demonstrating that the gaps between the rich and the poor have widened since the 1980s in many parts of the world. The very poor cannot usually buy the goods and services that global capitalists sell. While there is a long way to go before consumer demand inside the rich First World is entirely satisfied, the gap between the rich and the poor all over the world is not a welcome news for TNCs. In addition to the profits lost when poor people who want to buy goods and services do not have the money or even the credit to do so, the increasing visibility of the new rich and the new poor in an age of constant global media exposure directly challenges claims that everyone eventually benefits from capitalist globalization.

The ecological crisis is also directly connected with consumerism, encapsulated in the political and ideological struggles over the concept of sustainable development. Since the 1980s, most major TNCs have developed detailed policies in response to the challenges of environmental harm and declining stocks of resources essential for the maintenance of global capitalist consumerism. However, the persistence of problems of pollution, health risks, environmental degradation, and waste management intrinsic to the system suggests that it will be difficult to avoid fatal ecological crisis in the long term under the conditions of capitalist globalization. In this context, the attempt by TNCs and their supporters in international bureaucracies, the professions, government (globalizing politicians and officials at the national, international, and transnational levels), and the mass media to capture the idea of sustainable development and to reconcile it with capitalist globalization is worth further study (Sklair, 2001: Chapter 7).

This issue is inextricably bound up with the struggle between those who campaign for free access to information against those who deal in suppression and the dissemination of

disinformation, as recently exposed in the Wikileaks affair. While it has been on the agenda for at least the past 100 years, the issue of corporate spin and corporate lobbying has been receiving increased critical public and scholarly attention in the last decade in this context (Dinan and Miller, 2007).

The magazine, *New Internationalist*, reported in 2009 that 12 488 unique registered lobbyists actively lobbied the US Congress and Senate in the period January–July 2010; 15 000 Brussels-based lobbyists sought to influence European legislation, and 2600 special interest groups have a permanent office in Brussels. The lobbying industry employs around 14 000 people in Britain. In the United States, where lobbyists are more strictly monitored (although not necessarily regulated), between 1998 and 2010, over two billion dollars were spent by the pharmaceutical/health products industry, and over one billion dollars were spent on lobbying on behalf each of insurance, electrical utilities, business associations, computers/Internet, and oil and gas interests. These are large sums of money, even by US corporate standards, and it is significant that none of the biggest corporations in the lobbying industry has much of a public profile. While the industry leader, Burson Marsteller, has had some exposure due to its lobbying on behalf of repressive regimes (for example, Nigeria and Argentina in the 1970s) and corporate polluters (representing Union Carbide after Bhopal), the other major players have very low public profiles. For example, Hill & Knowlton (part of the global communications giant WPP), Fishbourne Hedges, Weber Shandwick, APCO, and Fleishmann Hillard, despite the fact that they all have substantial transnational portfolios, lobbying governments and the public on behalf of their corporate clients, are hardly known at all outside the industry. Nevertheless, it is probable that most of what we see and hear in the corporate mass media about global capitalism originates from lobbying companies and the public relations industry. Lobbyists also channel funds from corporations to politicians and political parties and other types of political entities in support of the election campaigns of friendly candidates, those who were identified above as the globalizing politicians and officials of the political fraction of the transnational capitalist class. Unfriendly candidates and officials are also targeted with promises of campaign funds and encouraged to become more corporate friendly.

Resistance to Global Capitalism

Global capitalism is often seen in terms of impersonal forces (notably market forces and free trade) wreaking havoc on the lives of ordinary and defenseless people and communities. It is not coincidental that interest in economic globalization has been accompanied by an upsurge in what has come to be known as New Social Movements (NSM) research. NSM theorists, despite their substantial differences, argue that the traditional response of the labor movement to global capitalism, based on class politics, has failed. In its place, a new analysis based on identity politics (notably of gender, sexuality, ethnicity, age, community, belief systems, and lifestyles) has been developed, directed toward resistance to sexism, racism, environmental damage, war-mongering, capitalist exploitation, and other forms of human rights abuses.

The globalization of identity politics involves the establishment of global networks of people with similar identities and interests outside the control of international, state, and local authorities. There is a substantial volume of research and documentation on such developments in the women's, peace, indigenous peoples, and environmental movements, some of it in direct response to perceived TNC malpractices. This provides a series of research-rich connections for scholars influenced by postmodernist and global capitalist theories.

Serious challenges to global capitalism in the economic sphere have also come from those who 'think global and act local.' This normally involves disrupting the capacity of TNCs and global financial institutions to accumulate what are widely perceived to be excessive private profits at the expense of their workforces, their consumers, and the communities that are affected by their activities. An important aspect of global capitalism is the increasing dispersal of the manufacturing process into many discrete phases carried out in many different places, popularized by Dicken (2007) as 'global shift.' Being no longer so dependent on the production of one factory and one workforce gives capital a distinct advantage, particularly against the strike weapon that once gave tremendous negative power to the working class. Global production chains can be disrupted by strategically planned stoppages, but this is generally more of an inconvenience than a real weapon of labor against capital. The global division of labor builds flexibility into the system so that not only can capital migrate anywhere in the world to find the cheapest reliable productive sources of labor but also few groups of workers can any longer decisively 'hold capital to ransom' (in the common slogan of the capitalist-controlled media) by withdrawing their labor. At the level of the production process, globalizing capital has a substantial advantage over labor. In this respect, the global organization of the TNCs and allied institutions like the World Bank and the WTO have generally proved to be too powerful for local labor and community organizations. Nevertheless, global capitalists, if one is to believe their own propaganda, are continuously beset by opposition, boycott, legal challenge, and moral outrage from the consumers of their products, concerned citizens, and by disruptions from their workers. There are also many ways to be ambivalent or hostile about the C-I of C, some of which the Green Movement has successfully exploited.

The issue of democracy is central to the prospects for global capitalism and the struggle against it. The rule of law, freedom of association and expression, and freely contested elections, as minimum conditions and however imperfectly sustained, are as necessary in the long run for mass market-based global consumerist capitalism as they are for alternative social systems to thrive. Most research on the democratic issues raised by capitalism, naturally, continues to be state-centrist, focusing largely on how it works within specific countries. Nevertheless, the growing influence of globalization in the social sciences appears to be encouraging more scholars to consider capitalism in the global as well as the local and/or national context and the prospects, however fragile at present, to effect changes in the system on a transnational and/or global basis as well as at the local and national levels. This is evidenced by the significant growth in research on transnational social movements, notably those that seek alternatives to the global

capitalist system (see Smith and Wiest, 2012). Resistance at the level of ideology is also flourishing, in particular contemporary Marxist analyses and critiques of the capitalist control of the media of mass communications (Fuchs and Mosco, 2012).

Alternatives to Global Capitalism

The crisis of global capitalism that began with the financial turmoil of 2008 unsurprisingly led to intensified debates around alternatives to capitalist globalization, not only in groups on the political extremes who have always been looking for alternatives to capitalism, but also to some extent by those in the more mainstream areas of political life all over the world. The antiglobalization movement that filled the media at the so-called battle of Seattle in 1999 and continued to gather pace during the first decade of the twenty-first century is slowly giving way to a rather more mature understanding that capitalist globalization is not the only possible form of globalization. Counterhegemonic globalization has been conceptualized in many ways, most usually in terms of a partial or complete rejection of capitalist globalization (Evans, 2012). Seeking alternatives to capitalist globalization, thus, does not mean rejecting generic globalization per se. It has been argued that capitalist globalization has undermined the emancipatory potential of generic globalization in terms of the electronic and postcolonial revolutions, the creation of transnational social spaces, and new forms of cosmopolitanism – and there are even signs that, despite its often problematic past history, ideas around socialist globalization are being revived (Sklair, 2009). Despite the daily barrage of propaganda from the corporate-controlled mass media and the message from most political parties in capitalist democracies that there is no alternative to global capitalism, serious research and practical programmes on realistic alternatives to it are underway. These range from radical rejections of global capitalism to progressive reforms of the existing system, from the traditional Marxist Left to the multifaceted World Social Forums, now with an organization hub in the United States.

The widespread appeal of the 'Occupy' movements became evident in September 2011 when, under the slogan of 'We are the 99%' the Occupy Wall Street campaigners appeared in Zuccotti Park in Manhattan. By October 2011, according to media reports, Occupy protests had taken place or were ongoing in almost 100 cities in more than 80 countries. In the United States alone, Occupy groups were reported to be active in over 600 communities. Unlike many previous anti-globalization protests, the Occupy movements have clearly targeted global capitalism as the problem. While actual occupations (notably in New York and in London) were forcibly ended, lively debates on the Internet and social networking media suggest that the process of movement building against capitalist globalization has sunk viable roots in many communities around the world. While there is little evidence that processes such as the 'Arab Spring' that emerged in 2011 contained any significant anticapitalist element, the extent to which they might eventually become and/or contribute to anticapitalist movements remains an open question. Certainly, phenomena like the mass mobilization of protesters in Tahrir Square in Cairo and in other places in North Africa and the Middle East inspired Occupy protestors everywhere. Other, less dramatic, initiatives, like the movement to create Transition Towns all over the world based on the principle of zero carbon economy and society, and various types of producer–consumer cooperatives, some under the aegis of the transnational cooperative movement and some not, have been given a considerable boost by extreme economic hardship brought on by the global financial crisis. The most interesting feature of these movements is that many of the participants appreciate not only the traditional values of localism, for example, sourcing food supplies as locally as possible, but also the possibilities of wider, even transnational linkages with other like-minded groups all over the world. The peasant-based movement, Via Campesina, provides some useful clues as to how such linkages might create nonexploitative mutually beneficial opportunities for sustainable standards of living, for example, in anticorporate struggles over food sovereignty. For those who participate in such movements and millions like them all over the world, alternatives to global capitalism are already emerging.

Capitalism: The History of the Concept

Jürgen Kocka, Free University of Berlin, Berlin, Germany

Abstract

'Capitalism' is a controversial concept. It emerged as a key concept of social criticism and as a concept for socioeconomic and historical analysis, in Western languages in the second half of the nineteenth century. The contributions by Marx and Hilferding, Sombart and Max Weber, Veblen and Keynes, Schumpeter and Braudel were particularly important. The concept played a role in controversial politico-ideological debates. Since the 1990s, a limited revival of the concept can be observed, but it is used more by social scientists and in the humanities than by economists. In conclusion, a working definition of 'capitalism' is suggested.

Origins: A Concept of Difference

'Capitalism' is a controversial concept. Many scholars avoid it, because they find it too ideological, value-loaded, vague, or broad. On the other hand, 'capitalism' has been a central concept for many important analyses and debates in academia and the general public. In the present time, it is increasingly used again, although, more by social scientists and in the humanities than by economists. If one wants to use it for scholarly purposes, one must define it and should know its history.

The concept 'capitalism' is a neologism, which emerged in Western languages in the second half of the nineteenth century. It is much younger than the historical reality it denotes and also younger than its major theoretical justifications. Neither Adam Smith and his contemporaries nor John Stuart Mill and the classical political economists used the concept. Certainly, 'capital' and 'capitalist' (as a noun and an adjective) were older and frequently used in European languages at least since the sixteenth and the eighteenth century, respectively. But the noun 'capitalism' appeared only after the European revolutions of 1848. The French socialist Louis Blanc (1811–82) used it in 1850 and defined it critically as "appropriation of capital by some to the exclusion of others." In 1851, Pierre Joseph Proudhon (1809–65) castigated landed property on the Parisian house market as a 'fortress of capitalism' when demanding public regulation against exorbitant rents and speculation. The same year, the liberal economist Frédéric Bastiat (1801–50) also quoted the term. In 1867, a French encyclopedia, the *Grand dictionnaire universel du XIXe siècle*, defined 'capitalism' as 'power of capital or capitalists.'

In German the concept was not pioneered by Karl Marx (1818–83) and Friedrich Engels (1820–95) who in the 1850s and 1860s wrote much about the 'capitalist mode of production' and 'capitalist accumulation,' but used the noun 'capitalism' only later and rather marginally. It was an economist with state socialist sympathies, Johann Karl Rodbertus (1805–75) who in 1869 wrote: "Capitalism has become a social system." In 1870, a liberal-conservative professor of economics, Albert Eberhard Friedrich Schäffle (1831–1903), published a voluminous monograph *Capitalism and Socialism*. He extensively dealt with the conflicts between capital and wage labor, advocated state-sponsored reforms in order to mitigate those conflicts, and defined 'capitalism' as a "national and international organism of production under the leadership of 'entrepreneurial' capitalists competing for highest profit." "The Socialists are correct," he added, "when they declare the present economy to be characterized by the 'capitalist mode of production,' i.e., by the hegemony of 'capitalism'." In 1872, the socialist Wilhelm Liebknecht (1826–1900) thundered against capitalism as a 'juggernaut on the battlefields of industry.' In 1876, a much read encyclopedia (Meyers Universal-Lexikon) mentioned 'capitalism' for the first time, while its 1896 edition carried a whole entry on the term defining it as the "capitalist mode of production in contrast to the socialist and collectivist one" (Hilger, 1982: 443f.; Kocka, 2013: 6–9; Bastiat, 1851: 407, 415; Rodbertus-Jagetzow, 1869: XVf.; Schäffle, 1870: 116; Silberner and Silberner, 1940).

In Great Britain, the concept was not unknown already in 1855, but then reluctantly introduced since the 1880s, especially in Fabian circles. John A. Hobson (1858–1940) published a book on *The Evolution of Modern Capitalism* in 1894 in which he concentrated on the rise of the factory system. The Encyclopedia Britannica mentioned the concept first in its 1910–11 edition (still in Capitalism) and carried a whole entry on the term in 1922 defining capitalism as "a system in which the means of production were owned by private proprietors who employed managers and workers for production." The history of the concept in the United States paralleled that of Great Britain, though there is evidence that the term was known to radical working-class circles before journalists and scholars adopted it. Here, Thorstein Veblen (1857–1929) was one of the first who used it in his *The Instinct of Workmanship* of 1914. He followed European authors when stressing that capitalism was much older than industrialization, growing out of the handicraft system, of trade and of financial businesses in the fifteenth and sixteenth century. But he emphasized that "its highest development comes with the advanced stages of the machine technology and is manifestly conditioned by the latter" (Pendennis, 1855: 75; Brick, 2006: 23–33; Veblen, 1914: 282–83, 302; Williams, 1976: 42–44; Merrill 1990, 470–473).

Individualized property rights; commodification on markets for goods, labor, land, and capital; the price mechanism and competition; investment, capital, and profit; the distinction between power holding proprietors and dependent property-less wage workers, tensions between capital and labor, rising inequality; the factory system; and industrialized

production – these were, in varying combinations, major characteristics of the concept 'capitalism' as it emerged until World War I. It was mostly used to denote an economic practice or an economic system, frequently with special attention to its social and cultural consequences.

To judge from German examples, the concept 'capitalism' emerged as a *concept of difference*. It was used to highlight, usually in a critical way, certain features of the then dominant or emerging socioeconomic reality *in contrast* to what this reality was thought to have been in previous ('precapitalist') times, and to what it might become under socialism in the future. It is remarkable how closely discourses about capitalism and socialism were interrelated. It is equally striking how much the capitalist elements of the contemporary reality – or the capitalist period in which one lived – were seen as something modern. In other words, many observers did not only discuss capitalism as they observed it, but they also placed it on an imaginary time line. The contrast with a selectively commemorated and frequently idealized past, as well as the contrast with an imagined and sometimes utopian future was constitutive for the emergence of the concept.

Critique and Analysis

While all authors saw capitalism in its developed form as a modern phenomenon, the concept was also used for historical research. It was applied to medieval and ancient Europe, i.e., to historical constellations in which capitalism was much less developed than in modern times or in the present. Werner Sombart (1902), Max Weber (1893–1908), Giuseppe Salvioli (1906), Henri Pirenne (1914), William Cunningham (1916), Richard Henry Tawney (1922), Henri Sée (1928), and many others participated in the frequently controversial exploration of distant pasts by using the modern category 'capitalism.' The findings of the Belgian economic historian, Henri Pirenne (1862–1935), have stood the test of the time best, while others like Sombart (1863–1941) exaggerated the static, noncapitalist, even anticapitalist spirit of the medieval period, in which, as recent research has shown, capitalist forms of behavior were not altogether alien to both long-distance merchants and market-related producers, in different regions of Europe – even before the spread of capitalist principles accelerated between the sixteenth and the eighteenth century (in long-distance trade, banking and finance, agriculture, and proto-industrialization) and industrialization got under way (since the eighteenth century).

It is more than obvious that 'capitalism' originated as a *polemical*, *critical* concept. Of course, there were those who defended capitalism on the basis of its economic strength, as a creator of wealth and welfare as well as a motor of modernization and a force of liberation from traditional bonds and hierarchies. However, among conservatives as well as on the political left, capitalism was seen as an irresistible force of erosion: custom was replaced by contract, *Gemeinschaft* by *Gesellschaft*, the traditional by the modern, social ties by the market. On the right, anticapitalism frequently went hand in hand with antiliberalism and antisemitism, particularly since the Great Depression of the 1870s. But the socialist critique of capitalism was the most powerful one. On the one hand, it attacked the exploitation of labor by capital, increasing social inequality, suppression at the work place, and the lack of a fair deal in the distribution of product and wealth. On the other hand, it predicted the decline of capitalism due to its internal contradictions and its eventual replacement by something new, namely socialism.

Because the concept 'capitalism' was frequently used for critical and polemical purposes, and because its definition varied between single authors a lot, many scholars stayed in distance to it or avoided it altogether. The economist Richard Passow (1880–1949) documented the lively discussion about the different meanings of the concept in the scholarly literature from the late-nineteenth century to the 1920s (1918/1927). But as it has happened so often with key concepts in the social sciences – 'bureaucracy,' 'democracy,' and 'modernization' can serve as examples – the value-loaded, mostly critical and even polemical use of 'capitalism' did not prevent, but sometimes even helped to turn it into a fruitful descriptive and analytical tool for scholarly purposes. Marx and Weber are two cases in point.

Marx did not only criticize the 'capitalist mode of production' and the 'bourgeois society' based on it. Together with Engels, he developed the building blocks of a critical theory of capitalism. Impressed by the victorious industrial capitalism of his time, he emphasized: (1) the market and its increasingly 'compulsive' laws; (2) the basic role of work and labor as well as the asymmetric relations and built-in tensions between capitalist employers and property-less wage workers to be transformed into the class conflict between bourgeoisie and proletariat; (3) investment, profit, accumulation, and endless expansion of the capitalist economy, which would spread over the world and transform social relations and dominant cultures, before being destroyed by its internal contradictions and being replaced by something new – socialism – in a revolutionary way. Marx' theories and visions have been sharply criticized. At the same time, they have influenced not only social movements, political parties, and historical developments, but also scholarly discourses and research more than the work by anybody else, ever since. Among his intellectual followers, Rudolf Hilferding (1877–1941) deserves particular attention who published *Finance Capital* in 1910. In his book, Hilferding transformed the Marxist analysis of capitalism in a way that it could deal with the rise of the modern corporation and the partial separation between ownership and control at its top, with the increasing tendencies toward concentration and centralization of capital as well as with the frequently close relation between industrial enterprises and banks. Hilferding developed the building blocks of a critical theory of 'Organized Capitalism' (his concept), which would not abandon the market as the basic regulatory mechanism, but would supplement and modify it by adding elements of collective coordination, structured negotiation, and conscious organization (Marx, 1967; Muller, 2003: 166–207; Hilferding, 1910; Winkler, 1974; Bottomore, 1985).

Classical Contributions

Max Weber (1864–1920) combined analysis and critique in another way. He conceptualized capitalism as a world-historical

phenomenon with many variations – merchant capitalism, political capitalism, spoils capitalism, among others – but he was primarily interested in *modern capitalism*, which he saw defined by the capitalist enterprise (*Unternehmung*) with its specific 'rationality,' its discipline, contractual wage work, division and coordination of labor as well as a clear separation from the households of the economic actors, including the entrepreneurs. Weber found *modern capitalism* in this sense only in the West, since about the sixteenth century. He analyzed its interdependence with important social, cultural, and political developments, particularly with legal change and the rise of the modern states in a long history of formation and coercion, negotiations, and wars. Weber emphasized that *modern capitalism* had indispensable economic presupposition, especially markets for goods, labor, and land as well as for money, credit, and capital. It also needed specific economic sentiments (*Wirtschaftsgesinnung*), which would motivate main actors to relentlessly strive and intensively work for innovation and profit, used not for consumption but for reinvestment with a perspective of long-term growth per se. Weber saw this 'capitalist spirit,' in its early phases, grounded in the ascetic religiosity of early modern Calvinists and Puritans. This 'Weber thesis' has been much criticized on empirical grounds. While Weber appreciated capitalism as a central pillar of Western modernity, he saw its built-in irrationalities, too. He doubted whether capitalism would lead to general welfare, and he feared that in the long run it might threaten human freedom (Weber, 1988, 2012; Parsons, 1928–29; Mommsen, 1997; Schluchter, 2009: 63–87).

By World War I historical and social science-based thought on capitalism had produced results, which have remained influential until the present. But over the next decades, economists, social scientists, and historians contributed major new thoughts to the discussion, which remained controversial, fluid, and stimulating.

For John Maynard Keynes (1883–1946), the concept did not play a central role, but he did not avoid it, either. In 1927, he saw "the essential characteristic of Capitalism" in its "dependence upon an intense appeal to the money-making and money-loving instincts of individuals as the main motive force of the economic machine." In some parts of Europe, but not in the United States, he observed a "latent reaction, somewhat widespread, against basing Society to the extent that we do upon fostering, encouraging, and protecting the money-motives of individuals." In contrast to Weber and Sombart who had emphasized the calculability and the rational instrumentality of capitalist behavior, he stressed the great importance of tempers, emotions, and 'animal spirits' in capitalism.

In the work of Joseph A. Schumpeter (1883–1950) who always enjoyed being outside the mainstream, 'capitalism' was a central category. He defined "that word which good economists always try to avoid: capitalism is that form of private property economy in which innovations are carried out by means of borrowed money, which in general … implies credit creation." On this basis, he assumed that capitalism began in Southern Europe around 1300. As the core of capitalism, Schumpeter famously discovered 'creative destruction.' Innovation on the basis of new combinations would lead to new methods of production and distribution, new forms of organization, new demand, and new economic opportunities, but also to the displacement or the destruction of older methods, patterns, and opportunities. There were always winners and losers. Schumpeter argued that booms and busts, ups and downs of the capitalist economy were related to the rhythms of innovation; he developed his theory of the business cycles on this basis. In the 1940s, Schumpeter was highly pessimistic as to the future of capitalism. He did not expect its failure due to internal contradictions and crises like Marx, but he observed capitalism's propensity to undermine itself: Its success would transform and weaken social and cultural forces – e.g., the middle class family, precapitalist elites, and the protection by a powerful state – which capitalism had needed and would need for its ascent and survival (Keynes, 1927: 50f.; Schumpeter, 1939: 223f.; 1976).

In his monumental *Civilisation matérielle, économie et capitalisme* (1967–1979), Fernand Braudel offered an alternative definition by sharply distinguishing 'capitalism' from 'market economy.' He saw local markets, fairs and stores, the everyday practice of exchange by producers, traders, and consumers as constitutive for market economies throughout the ages and nearly everywhere in the world, while he tried to reserve the term 'capitalism' to the businesses of a relatively narrow and exclusive superstructure of wealthy and influential merchants, bankers, ship owners, proprietors, entrepreneurs, and financial capitalists. Among them, competition played minimal, close contacts to the holders of political power – princes, bishops, magistrates, and governments – an important role. While Braudel's contraposition of 'market economy' and 'capitalism' has met many insurmountable problems, it had the merit of highlighting that oligopolistic and monopolistic practices have always been frequent in capitalism, and that a close symbiosis between capitalists and the politically powerful has been much more the rule than their clean separation. Braudel also further developed the tradition of seeing capitalism as a world-historical development. He influenced authors like Immanuel Wallerstein and Giovanni Arrighi, who in the last quarter of the twentieth century conceptualized and investigated capitalism as a global phenomenon. Wallerstein built on older theories of imperialism and *dependencia* when placing capitalism into the center of his 'world-system approach.' Arrighi stressed finance capitalism and proposed a scheme according to which capitalist *lead regions* have changed over time and moved from Northern Italy in the late-middle ages via the Netherlands in the early modern period and England since the eighteenth century to the United States (twentieth century), and perhaps China in the future (Braudel, 1967–1979; Wallerstein, 1974; Arrighi, 1994, 2007; Vries, 2012).

Political Contexts and Recent Revival

No doubt, 'capitalism' has always been more than a political catchword or instrumentalized slogan. Scholarly definitions, clarifications, and application have made the term a penetrating and far-reaching analytical instrument, ever since the nineteenth century. But the term has preserved part of its affinity to social criticism. Over the decades it has frequently,

though not at all exclusively, been used by authors who saw themselves somewhere on the left and combined analysis with criticism in varying combinations when writing about economy, society, politics, and culture. For illustration, consider economic interpretations of imperialism (e.g., Luxemburg, 1913), studies on monopoly capitalism (Baran and Sweezy, 1966), treatises on the relation between the crisis of capitalism and the rise of fascism (e.g., Poulantzas, 1974), critical comments about the internal contradictions of capitalism (Habermas, 1973; Bell, 1976; Boltanski and Chiapello, 2000), the need for reembedding capitalism in order to make it more compatible with human needs (Polanyi, 1944; Streeck, 2009), or reflections on how capitalism will cope with present-day challenges like the hypotrophy of finance capitalism, increasing social inequality, or climate change (Wallerstein et al., 2013). Analysis and criticism can reinforce each other.

In addition, the term 'capitalism' has continued to play a role in controversial political debates in the public arena, reaching far beyond academic discourses. 'Capitalism' has been a central combat term within socialist and communist rhetoric and propaganda, sometimes ambitious and pointed, frequently simplified, aggressive, and totalizing. As a consequence, the term got involved into and damaged by the political and ideological struggles of the past century. 'Capitalism' was a key word in deep-reaching conflicts between different positions on the left and various shades of the right as to the correct or desirable economic, social, and political shape of the future. It played a role in controversies between democratic speakers and the advocates of both left- and right-wing dictatorships. It has been shown how the deep tension between the United States and the Soviet Union after World War I and later on between West and East in the Cold War influenced and flavored the public use of the term 'capitalism' in the United States (Marks, 2012). The Cold War impacted politics, culture, and language in most European countries, too. Again, 'capitalism' served as a concept of difference. It was defined and applied in contrast to the Communist alternative and challenge. This sometimes led to dichotomic simplifications and distortions. The more 'capitalism' was used as a polemical catchword in politico-ideological conflicts, the less useful it appeared to many scholars. Consequently they criticized or avoided it altogether (Sombart, 1935: 195; Hayek, 1954; Hartwell, 1983; Grassby, 1999).

Since the 1990s, something like a limited revival of the concept can be observed, within general discussions as well as in the social and historical sciences (Sklansky, 2012). On the one hand, the Cold War is over. Nowadays 'capitalism' is much less a combat term in a systemic conflict of global scale than it used to be during most of the twentieth century. The concept has been freed from this burden. On the other hand, a resurgence of market liberalism if not of laissez-faire capitalism has taken place since the late 1970s, primarily on the level of neoliberal discourses, but partly also in economic and social policy (Harvey, 2007). Between World War I (at the latest) and the 1970s, powerful trends toward more political coordination of markets, more planned organization of competition, and more welfare state intervention had been on the way, at least in parts of Europe and North America. Some observers spoke of a move toward 'organized capitalism,' others argued that a transition from nineteenth century industrial capitalism to a 'mixed system' or a postcapitalist era was on the way (Brick, 2006: 54–85). In the increasingly neoliberal atmosphere and the waves of deregulation since the 1970s – at least in the United States and in some parts of Europe (including Eastern Europe since the 1990s) – this perspective has lost much credibility. In some parts of the intellectual spectrum, 'capitalism' had always been used in an unconditionally positive sense, at least in the United States (e.g., Friedman, 1962). Now, the affirmative (e.g., Mackey, 2013) or strictly neutral usage (e.g., Hall and Soskice, 2001) of the term gained additional ground. The Great Recession of 2008 had – *thirdly* – an opposite effect. It led to a renewed questioning of the neoliberal belief in the self-regulating capacities of capitalist markets and to new proposals in favor of reregulation. But it also contributed to rising interest in the term 'capitalism.' *Fourthly*, the accelerated globalization of capitalism in the last decades has demonstrated that capitalism can flourish in very different social contexts and under very different political regimes, even in authoritarian and dictatorial systems, at least for a while. A well-defined concept of 'capitalism' appears to be well suited for guiding comparative research on a global scale, now on the agenda. Global perspectives enlarge the typology of observable forms of capitalism. They question received theses, e.g., with respect to the relation between bonded labor, wage labor on a contractual basis, and capitalism. They reopen the debate on the relations between capitalism, freedom, and democracy (Pryor, 2010: 74–111; van der Linden, 2008; Sanyal, 2007).

A Lean Definition

The definitions of capitalism will vary with different topics and different research priorities. In the light of the previous survey, and if a broad systematic and historical analysis of capitalism is intended, a working definition is useful, which emphasizes decentralization, commodification, and accumulation as basic characteristics. On the one hand, it is essential that individual and collective actors dispose of rights, which enable them to make economic decisions in a relatively autonomous and decentralized way. On the other hand, markets serve as the main mechanisms of allocation and coordination; commodification permeates capitalism in many forms, including the commodification of labor. Thirdly, capital is central, that means utilizing resources for investment in the present with the expectation of higher gains in the future, accepting credit besides using savings and returns, dealing with uncertainty and risk as well as having profits, and accumulation as aims. Change, growth, and expansion are inscribed (Kocka, 2010, 2013).

Such a lean definition allows to distinguish between very different types of capitalism and to study the ways in which they have changed and mixed. It also allows to trace capitalist phenomena in epochs and regions in which they were or are just minority phenomena within dominantly noncapitalist environments while acknowledging that to speak of capitalism as an economic *system* its mechanisms must be fully developed and dominant. While such a definition concentrates on economic criteria, it also directs attention to the numerous,

changing, and changeable social, political, legal, and cultural conditions and consequences of capitalism. While the term has been used and can be used for the analysis of very specific problems – like the change from entrepreneurial to managerial capitalism in the history of modern firms (Chandler, 1977; John, 2008) – it has been and can be particularly useful as a frame within which to study the changing interconnections between economic, social, legal, political, and cultural dimensions (e.g., Zakim and Kornblith, 2012). The term can serve as a tool for bridging boundaries between disciplines.

Throughout its history, the concept has been used for relating specific objects of study to grand questions of the past, present, and future, questions in which normative orientations play a role. In this respect, the term 'capitalism' resembles concepts like 'modernity' or 'democracy.' The term 'capitalism' emerged as a critical *concept of difference*, contrasting observations of the present with constructions of different pasts and imaginations of a future, which would be different again. Criticism and analysis have been closely intertwined. While this accounts for some of the problems and weaknesses of the concept, it also explains some of its particular strengths and its continuous attraction. Today, it is not at all clear how an alternative to capitalism could and should look like. People who use the concept surely diverge as to their personal and political visions of the future. But some, though vague, idea or protovision about how things could and perhaps should be, differently from the present, seem to be in the back of the head of some of those who use the term 'capitalism' to talk about the past, present, and future. In this sense, the critical potential of the concept has not fully disappeared, while not exacerbating empirical description and theoretical analysis.

Abstract

Because of rising prevalence rates of coronary heart disease and chronic heart failure, an increasing number of persons have to cope with cardiac disease. This article gives an overview of stress and coping concepts applied in the domain of adult heart disease. Approach-oriented coping strategies and pursuing goals in life appear to protect cardiac patients from negative emotions. Rumination, however, appears to contribute to the development of depressive symptoms. Interventions should consider patients' dispositional coping styles. Methodological limitations and suggestions for future research including prospective designs and objectively assessed outcomes in the area of cardiac diseases are outlined.

Introduction

Cardiac diseases constitute a major health problem worldwide. Coronary heart disease (CHD), myocardial infarction (MI), and chronic heart failure (chronic HF) are the main contributors to this disease burden. Chronic HF denotes a clinical syndrome that can result from any structural or functional cardiac disorder that impairs the ventricles' ability to fill with or to eject blood, such as CHD and MI (Hunt et al., 2009). This article focuses on coping processes in adults with the most common cardiac conditions, CHD and chronic HF. Stress and coping are defined, and research regarding associations of coping styles and strategies with outcomes investigated cross-sectionally and longitudinally will be reviewed.

Persons who cope effectively with stressful encounters are expected to report good well-being, few psychological problems, a good quality of life, and, importantly, also good physical health (Lazarus, 1993). Thus, we give an overview about associations of coping styles and strategies with emotional outcomes including depression and post-traumatic stress disorder (PTSD), behavioral outcomes such as resuming walking, and medical outcomes including mortality. In the concluding section, open questions and directions for future research are outlined.

Definitions of Stress and Coping in Cardiac Disease

Stress and coping in the context of cardiac disease are typically conceptualized according to the transactional stress and coping theory by Lazarus and Folkman (1984). Psychological stress is defined as "a particular relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being" (Lazarus and Folkman, 1984: p. 19). According to Lazarus and Folkman (1984), the way a person appraises situations determines both stress reactions and coping efforts. Coping in this situational approach is defined as "constantly changing cognitive and behavioral efforts to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person." (Lazarus and Folkman, 1984: p. 141). In order to evaluate which type of coping is beneficial for cardiac patients' adjustment, it is important to note that the term 'coping' refers to all efforts to deal with a stressful encounter, independent of their effectiveness (Lazarus and Folkman, 1984).

Lazarus (1993) emphasizes that when studying how patients cope with their illness, it is important to specify the particular threats the patient is experiencing at that time, rather than focusing on the illness in general. In line with this reasoning, specific stressors experienced by patients with CHD and chronic HF have been identified. Survivors of an MI report distress due to the emotional impact of the disease, life style changes, dealing with health professionals, reactions of the partner, changes in roles of social life, return to work, financial difficulties, and dependency (e.g., Stewart et al., 2000). Similar stressors have been reported by patients with chronic HF (Bosworth et al., 2004; Spaderna et al., 2012). Additional stressors comprise the disease's interferences with personal goals (Garnefski and Kraaji, 2010) or medication side effects (Bosworth et al., 2004). In addition to disease-related stressors, patients also encounter common stressors such as death of a loved one or children's problems (Bunyamin et al., 2013). Considering that perceived stress contributes to future adverse events and reduced long-term survival in patients with cardiac disease (e.g., Aboa-Éboulé et al., 2007; Arnold et al., 2012), identification of dispositional coping styles and actual coping strategies that promote successful adjustment is crucial.

Coping styles refer to stable personality dispositions that determine a person's typical way of responding to stressful encounters. These approaches often are based on theoretical distinctions of approach versus avoidance of threats. Trait approaches of coping that have been applied to cardiac patients include sensitization/repression (Weinberger et al., 1979) and vigilance/cognitive avoidance (Krohne, 1993). Others postulated a broader set of possible coping dimensions. For example, Carver et al. (1989) developed the Coping Orientation to Problem Experience (COPE) to assess 14 different dispositional coping strategies persons usually adopt in stressful situations.

According to the situational coping approach of Lazarus and Folkman, the COPE can also be used to assess which of various coping strategies were actually applied in a specific situation (Carver et al., 1989). This instrument has been widely used with cardiac patients, both in its dispositional and actual version. Other self-report instruments to assess coping strategies exist. Importantly, these instruments cover a different range of actual coping behaviors, and yield different strategies.

Although the term 'strategy' implies that persons pursue specific goals when dealing with a stressor, these goals generally are not part of the assessment.

Dispositional Coping Styles in Cardiac Disease

Coping Styles and Emotional Well-Being

It has been argued that a repressive coping style might be beneficial in the short run, but might undermine necessary cognitive and behavioral adaptations to the illness, thereby leading to adverse outcomes in the long run (Suls and Fletcher, 1985). According to these expectations, cross-sectional empirical evidence indicates that cardiac patients with an avoidant coping style reported less negative affect, more positive affect (Bedi and Brown, 2005), and lower distress and depressive symptoms than patients with a nonavoidant coping style (Denollet et al., 2008). Similarly, cognitive avoidance was related to better emotional quality of life (but unrelated to physical quality of life) in patients newly listed for cardiac transplantation, whereas vigilance, i.e., directing attention toward threatening information, was accompanied with worse quality of life (Bunyamin et al., 2013).

A longitudinal study by Ginzburg et al. (2002) contradicts the assumption that a repressive coping style leads to negative emotional long-term consequences. Repressors not only showed less-severe acute stress disorder than high-anxious and defensive patients 1 week after their MI, but were also less likely than nonrepressors to be classified as having clinical PTSD (7% vs 17%, 19%, and 20% in the other three coping style groups) 7 months later. Repressors also reported lower symptom levels independent of education, prior traumatic events, and acute stress disorder (Ginzburg et al., 2002). Interestingly, repressors and nonrepressors did not differ in their primary appraisals, i.e., in their threat perception of the MI or their medical status (Ginzburg et al., 2002). Replications and data from studies with a longer follow-up are warranted in this area.

Assessing denial via the dispositional version of the COPE, on the other hand, was unrelated to emotional well-being as indicated by depressive symptoms after 2 years in 83 patients with chronic HF (Murberg et al., 2002). However, behavioral disengagement (i.e., giving up attempts to attain goals) predicted higher depression scores, even after controlling for sex, age, neuroticism, extraversion, and New York Heart Association (NYHA) class, and indicator for disease severity, which is based on patients' self-reports (Murberg et al., 2002). Thus, diverting attention from threats should be distinguished from behavioral disengagement.

Coping Styles, Medical Outcomes, and Mortality

An avoidant coping style appears to help patients to maintain positive affect and to prevent negative affect and stress. However, one study indicates that avoidance (repression) might be associated with impaired survival in the long run. After a mean follow-up of 6.6 years, repressors had a two-fold risk of death or nonfatal MI compared to nonrepressors, even after statistically controlling for covariates including disease severity at baseline (Denollet et al., 2008).

There is some evidence that not an avoidant coping style itself, but the incompatibility of information or interventions with a patient's coping style, are detrimental to patients' physical health. Early evidence regarding the adverse effect of risk information on cardiac patients' health status comes from a small study of 97 patients who had received percutaneous coronary transluminal angioplasty (PCTA) (Shaw et al., 1986). Sensitizers (see Weinberger et al., 1979) were at higher risk for restenosis 6 months later when they had little knowledge about procedural and risk factors, compared to sensitizers who had a high level of information. Regarding additional medical complications 6 months after PCTA (e.g., hospitalization for chest pain, MI, arrhythmias), repressors with a high level of information were more likely to have complications than repressors with low-information level. However, this finding applied only to patients with no prior history of heart attack (Shaw et al., 1986).

A mismatch of patients' coping style with psychosocial treatment can even challenge survival. In the Montreal Heart Attack Readjustment Trial, 1.376 patients were randomized to control or treatment, with the latter consisting of monthly telephone calls to monitor patients' distress (Frasure-Smith et al., 2002). If a patient reported elevated distress or was rehospitalized, he or she received a home-based nursing intervention. In the treatment group, both men and women with a repressive coping style had a two-fold mortality risk compared to repressors of the control group, even after 5 years of follow-up (Frasure-Smith et al., 2002). By the end of the 1-year intervention program, repressors of the treatment group were more likely to be prescribed benzodiazepines and to have had emergency room visits than those in the control group. They also tended to report more somatic depression symptoms. On the contrary, for men who qualified as truly anxious (i.e., high anxiety regardless of social desirability), the intervention was beneficial, which was mediated by reductions in somatic depression symptoms (Frasure-Smith et al., 2002). The authors conclude that their intervention interfered with repressors' coping style, undermining their need to avoid perceptions of distress. Thus, interventions aiming at distress regulation should be tailored to a patient's coping style (Frasure-Smith et al., 2002).

Summary

In sum, the few studies available to date indicate that among patients with CHD and advanced chronic HF, those with an avoidant coping style, i.e., a disposition to avert attention from threats, do better in terms of emotional well-being and quality of life than nonrepressors or persons who score high on vigilance or sensitization. Repressors appear also to be at lower risk to develop PTSD. However, they might be at increased risk for medical complications, additional MIs, and premature death in the long run, particularly if they cannot cope according to their favored style, i.e., if they are forced to focus on distress and risk factors. Sensitizers, on the contrary, appear to benefit from information that helps to reduce their anxiety.

Actual Coping Strategies in Cardiac Disease

Coping Strategies and Depression

During the last decade, it has been consistently observed that 20–40% of patients with CHD and chronic HF are clinically

depressed or experienceelevated depressive symptoms (Celano and Huffman, 2011). As depression is independently related to an impaired prognosis in CHD and chronic HF (Celano and Huffman, 2011), even among patients with advanced disease who are listed for cardiac transplantation (Spaderna et al., 2014), researchers started to investigate whether specific appraisals and coping strategies are related to the development of clinical depression or depressive symptoms in these patients.

Threat Appraisal

Threat appraisals, i.e., appraising disease-related stressors as harmful to one's physical and emotional well-being, have been cross-sectionally linked to a diagnosis and to symptoms of depression in patients hospitalized because of an MI (e.g., Vögele et al., 2012). Longitudinally, threat appraisal contributed to the development of depressive symptoms after 6 months in patients with chronic HF, whereas challenge appraisal was unrelated to depression (Park et al., 2006).

Approach versus Avoidance Coping Strategies

Contrary to findings regarding coping styles, avoidance coping strategies and depressive symptoms occur together (e.g., Vollman et al., 2007). In contrast, approach-oriented coping strategies such as planful problem solving and seeking social support were negatively related to depressive symptoms (Vollman et al., 2007).

Regarding the development of depressive symptoms, prospective studies indicate that avoidance strategies are irrelevant (e.g., Schröder et al., 1998). van Elderen et al. (1999), who measured *cognitive* approach and avoidance coping in 278 patients with CHD, observed neither any cross-sectional nor longitudinal relationships between avoidance (assessed by items such as "If I'm worried about my heart disease … I try to keep my mind off it"; "I think that worrying about it doesn't make much sense") and depressive symptoms. Approach coping, however, was cross-sectionally related to higher depressive symptoms (and state anxiety), and longitudinally (3 and 12 months later) to lower depression (van Elderen et al., 1999). The latter result is surprising, considering that approach coping was operationalized via items such as "I allow myself to be controlled by it (heart disease)" or "I think how easy it is for healthy people", self-blaming and viewing the world pessimistically, indicating a rather passive approach to the stressor. A composite labeled 'active coping' also helped to counter depressive symptoms assessed after 6 months in patients with chronic HF (Park et al., 2006). This might be particularly relevant for those patients who perceive their health condition as controllable (Park et al., 2012).

Garnefski and Kraaji (2010) emphasized that approaching the stressor 'cardiac disease' by finding new goals in one's life (goal reengagement) contributes to a stable low level of depressive symptoms. In the study by Vögele et al. (2012), the coping strategies 'threat minimization' and 'search for affiliation' were associated with lower depression scores immediately after the MI and up to 6 months later (Vögele et al., 2012). Interestingly, patients who perceived higher threat reported to make less use of these strategies (Vögele et al., 2012). Social coping was also related to fewer depressive symptoms and more energy after surgery in the study by Schröder et al. (1998). However, these studies cannot explain by which means (avoiding or approaching the problem) threat is minimized and, similarly, if patients seek social contacts in order to avoid threat or to approach it together with the support of others.

In sum, cardiac patients who are also depressed, report to make less use of active approach coping strategies such as problem solving or reframing, and, at least in some studies, report to adopt more avoidant strategies and self-blaming. The finding that depression is accompanied by the adoption of passive coping strategies, less reframing, more self-blaming, and viewing the world pessimistically, is not surprising and could be conceived as part of the depressive disorder's symptomatology. Based on the few longitudinal studies, it appears that avoidance strategies are irrelevant for the development of depression, whereas approach coping, but also seeking social support helps to diminish depressive symptoms. The discrepancy of findings regarding avoidant strategies (often accompanied by higher depression) and an avoidant coping style (associated with lower reported depression) deserves more attention.

Rumination

In a different approach to explain the development of depression in cardiac patients, researchers have focused on specific coping strategies, particularly rumination. This construct has been defined as "behaviours and thoughts that focus one's attention on one's depressive symptoms and on the implications of those symptoms" (Nolen-Hoeksema, 1991, p. 569). Recent studies did find support for the relevance of rumination both for self-reported cardiac symptoms such as fatigue or sleep problems (León et al., 2010) and for depressive symptoms (e.g., Garnefski and Kraaji, 2010), although not consistently. Schröder and colleagues found that those patients who had often used rumination as a coping strategy during the month before their cardiac surgery reported more depressive symptoms, reduced energy, and more worries about their infarct, functioning, and symptoms in the week after cardiac surgery than those patients who had adopted rumination infrequently (Schröder et al., 1998). However, Vögele et al. (2012) did not observe any associations of rumination with future depression (self-reported and clinically diagnosed according DSM-IV) in patients after an MI.

It is conceivable that the nature of ruminative thoughts and additional factors such as existing depressive symptoms and vulnerabilities (Denton et al., 2012) need to be taken into account to explain the development of depressive symptoms. In 387 patients who showed no signs of depression after an acute coronary syndrome, not brooding rumination (e.g., "I think, what am I doing to deserve this?") per se, but it's interaction with depression vulnerabilities predicted depressive symptoms 3 months later. That is, only when vulnerabilities such as dysfunctional beliefs, few pleasant events, or poor dyadic adjustment were also present at baseline, rumination did predict an increase in depressive symptoms. In patients who already showed elevated depression scores at baseline, rumination directly predicted depression severity 3 months later (Denton et al., 2012). Reflective rumination (e.g., "I analyze recent events to understand why I am depressed") was generally unrelated to depression (Denton et al., 2012). Thus, rumination contributes to the development of depression in cardiac patients, yet mechanisms might be more complex than originally expected.

Coping Strategies and Anxiety

Anxiety was found to be a common emotional response to heart failure due to the unpredictable nature of the disease (Bosworth et al., 2004) and it has also been linked to an increased risk of cardiac events (Frasure-Smith and Lespérance, 2008). Yet, the few studies available to date yield inconsistent findings regarding the association of coping strategies with anxiety.

Cross-sectionally, a frequent use of avoidant coping strategies was linked to higher anxiety and to a stronger relationship of anxiety with poor physical functioning in the study by Eisenberg et al. (2012), whereas van Elderen et al. (1999) reported associations of avoidant coping with lower anxiety and higher well-being at baseline. In this study, avoidant coping did not predict negative emotions later on, although patients, on average, reported to use more avoidant than approach coping.

With regard to approach coping strategies, results are also inconsistent. Approach coping strategies were unrelated with anxiety (Eisenberg et al., 2012), while anxious CHD patients reported less problem-focused coping in the study by Tung et al. (2008). Approach coping, on the other hand, was cross-sectionally associated with higher anxiety, and longitudinally with lower anxiety (and depression) (van Elderen et al., 1999). Thus, it is unclear whether approach coping is accompanied by negative affect in the short run, but pays off with reduced anxiety in the long run. More prospective studies are needed to establish such mechanisms.

In sum, the few studies examining the relationship of anxiety and coping activities yield inconsistent results, which might in part be explained by use of different operationalizations of avoidant and approach coping strategies. In addition, depression and anxiety are often highly correlated and it remains unclear if these emotional states or disorders are differentially related with coping.

Coping Strategies and Behavioral Outcomes

Resuming an active life after MI is an important goal of rehabilitation. However, the role of coping for achieving functional outcomes, e.g., return to work, in patients with cardiac disease has not received much attention. Schröder et al. (1998) investigated associations of coping with behavioral indicators of resuming an active life after cardiac surgery. Patients' self-reports regarding activities such as resuming reading, ambulating in the ward, and efforts to regain physical fitness were assessed in the week after surgery. Higher scores in rumination before surgery were associated with a longer stay in the intensive care unit, and a delayed resumption of reading, walking, and visits. Patients who often sought for information started walking later. Social coping, i.e., seeking social contacts and support, was associated with faster recovery regarding reading and ambulation (Schröder et al., 1998).

Coping Strategies and Medical Outcomes

Regarding associations of coping with indicators of disease severity, results of cross-sectional studies consistently show that coping strategies are unrelated to objectively assessed indicators of disease severity, such as degree of obstruction of the coronary arteries (León et al., 2010), number of bypasses, infarcts, medication (Schröder et al., 1998), or left-ventricular ejection farction (Park et al., 2006, 2012). It appears that coping efforts are not restricted by disease severity. Whether the adoption of certain coping strategies in specific stressful encounters is related to medical outcomes remains elusive.

Summary

In sum, it appears that appraising situations as threat instead of challenge contributes to future depression in patients with cardiac disease. In addition, ruminating about stressors and the disease may further increase the risk for depression, particularly if rumination is of the brooding kind and additional vulnerabilities are present. Avoidant coping strategies are accompanied with psychological distress and negatively associated with subjective well-being in patients with CHD and chronic HF, but this type of strategies appears to be of less relevance regarding future depression. It is conceivable, however, that once patients are depressed they tend to rely on avoidant coping strategies more often than nondepressed patients. Active coping on the other hand, an approach strategy, appears to counteract depressive symptoms. Social support and other resources might assist patients to apply coping strategies that are more effective with regard to impairing depression. However, results are heterogeneous due to different conceptualizations of coping styles and strategies and suboptimal study designs. Larger longitudinal studies are needed to elucidate the relationships between appraisal, adoption of coping strategies, and the development of depression and anxiety after MI and in patients with chronic HF. Moreover, studies investigating the impact of coping strategies on behavioral outcomes are warranted.

Future Directions

Coping styles and strategies are worth to be considered in cardiac disease. Because there is neither a generally accepted definition of coping styles and strategies nor agreement regarding their measurement, instruments yield assessments of coping constructs with different structures and varying numbers and types of strategies. Some authors use the terms 'style' and 'strategy' interchangeably, or they conceptualize coping in terms of a disposition while assessing it by an instrument designed to measure strategies. In addition, some researchers rely on idiosyncratic repertories of coping concepts, often derived from factor analysis of very small samples. Also, in some studies, different coping subscales are merged to a composite measure, either based on correlational patterns or theoretical presumptions. In consequence, despite using the same instruments and labels, the underlying subscales might differ considerably. Thus, inconsistencies may simply result from the heterogeneous use of coping terms and inadequate operationalizations of the coping constructs under investigation.

Inconsistencies in findings may also result from different operationalizations of stressors. In some studies, the instructions are adapted to the domain of cardiac disease, yet some mention only the disease itself, while others specify distinct stressors such as angina symptoms. In other studies, it remains unclear if patients had to refer to a specific stressor at all. As has

been shown, cardiac patients report a variety of disease-related stressors and, additionally, are exposed to stressors that are not directly related to their disease. Therefore, types of stressor and situational characteristics such as controllability of the stressor need to be taken into account when evaluating coping efforts. However, this goodness-of-fit-hypothesis was rarely considered (e.g., Park et al., 2012). Furthermore, to better understand possible causal mechanisms, more studies applying longitudinal or experimental designs are recommended.

Moreover, future studies could benefit from addressing a broader range of outcomes. Particularly medical outcomes such as cardiac events, rehospitalizations, and survival as consequences of coping need to be examined in prospective studies. In relation to disease-related stressors, behavioral indicators such as resuming daily activities or returning to work deserve more attention. In addition, positive outcomes in cardiac disease such as a greater appreciation of life, greater sense of personal strength, or spiritual development are understudied in these patients. Future studies should also explicitly explore potential gender differences in coping with cardiac disease.

With regard to psychosocial interventions to improve patients' coping efforts, not much is known except for the importance to consider patients' coping styles. Stress management is often part of psychological interventions for cardiac patients (Linden et al., 2007), but its components vary from teaching of specific cognitive coping strategies to relaxation techniques, yoga, and support groups. Although comprehensive psychosocial interventions including dietary changes and regular exercise have been shown to benefit cardiac patients (Linden et al., 2007), no conclusion with regard to specific coping strategies can be drawn. Psychological interventions to decrease depression in cardiac patients mostly rely on problem solving and cognitive behavior therapy and are able to reduce depression, although effect sizes are small (Dickens et al., 2013).

Conclusion

Patients with cardiac diseases experience illness-related and common stressors, and, in addition, prolonged stress experience appears to predict additional adverse events and mortality. However, current knowledge regarding effective ways of coping for cardiac patients is limited by a variety of different coping concepts, operationalizations, and limited research designs. Patients with an avoidant coping style divert their attention from threats and therefore report less depressive symptoms than nonrepressors and are at reduced risk for developing PTSD. However, prognosis might be impaired if patients' coping styles are undermined by highlighting potential problems and risks, and providing information for repressors, and withholding important information for sensitizers, respectively. Approaching stressors, adopting active coping strategies, and developing new goals appear to counteract depressive symptoms in cardiac patients. Brooding rumination, on the contrary, might promote the development of depressive symptoms, particularly if additional risk factors for depression are present. In sum, more research is needed to address relevant issues of coping in cardiac disease. Studies should be based on theoretical approaches and apply a sound assessment of coping and related variables. Prospective research designs and randomized controlled trials examining medical and behavioral outcomes with varying time frames are warranted. This can help to elucidate the impact of appraisal processes, coping strategies, and styles on adjustment in men and women with cardiac diseases.

Cardiovascular Reactivity and Recovery

Joseph P Gyekis and William Gerin, Pennsylvania State University, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Acute mental stress leads to transient blood pressure (BP) and heart rate elevations, and these are risk factors for the development of hypertension and heart disease. A corollary is that individuals particularly prone to strong cardiovascular reactivity (CVR) in the lab may experience these responses frequently enough in daily life for these elevations in BP to directly contribute to tissue damage and the occurrence of cardiovascular disease events. In this article, we provide a guide to the methodology of CVR studies. Following a brief review of the empirical literature, we discuss issues regarding the design, implementation, and analysis of reactivity studies.

Introduction

The cardiovascular system is tightly regulated to control the flow of gases and nutrients throughout the body. The circulatory functions of the heart and blood vessels change in response to chemical signals within the blood stream as well as innervation to their tissues from the nervous system. Within the realm of psychology, cardiovascular reactivity (CVR) specifically refers to the degree to which an individual experiences changes in cardiovascular function in response to engaging, challenging, or aversive behavioral situations, especially those that are mental in origin (Manuck, 1994).

Nearly a century of research on CVR has shown that acute mental stress leads to transient changes in a spectrum of cardiovascular responses – prominent among them a characteristic elevation of heart rate and blood pressure (BP) in most individuals experiencing psychosocial stress in the laboratory. Researchers hypothesize that individuals particularly prone to strong CVR in the lab may also experience these responses frequently enough in daily life for these mental challenge-related elevations in BP to directly contribute to tissue damage and the occurrence of cardiovascular disease events (Manuck, 1994). Thus, researchers have proposed that CVR might be a mechanism linking behavioral and psychosocial factors such as anger, hostility, Type A personality, lack of social support, and exposure to cardiovascular diseases.

The purpose of this article is to update a prior article (Goyal et al., 2008) and provide a guide for researchers interested in conducting studies of CVR. Following a brief review of the empirical literature, we discuss issues regarding the design, implementation, and analysis of reactivity studies.

CVR as a Possible Cause of Cardiovascular Disease

Unlike profound risk factors that consistently show large effects on disease outcomes, studies on the role of CVR on future disease outcomes are mixed and study-specific. Chida and Steptoe (2010) recently conducted a meta-analysis on prospective studies of the relationship between CVR and subclinical and clinical endpoints. They found that although studies varied substantially, overall there were significant effects of CVR on various outcomes, especially for future development of hypertension. Although only about 1% of the variability in outcomes was explained by laboratory tests of CVR, this 1% is deemed to be clinically significant because even incremental increases in hypertension risk lead directly to increases in risk of cardiovascular events.

Since findings regarding the generalizability of laboratory CVR to the natural environment have been inconsistent (Gerin et al., 1994; Harshfield et al., 1988; Ironson et al., 1989; Kamarck et al., 2000, 2003, 2005; Turner et al., 1994), it seems possible that the true effect of real-world CVR on cardiovascular disease events may be stronger than those derived from laboratory measures.

In recent years, improvements in technology are making it possible to investigate whether CVR to daily stressors better predict future hypertension and cardiovascular events. However, studies employing ambulatory BP monitoring of CVR to natural stressors recorded by ecological momentary assessment are still in the proof of concept stage, and have not been followed up long term to evaluate their prospective utility. These studies are urgently needed to evaluate whether real-life CVR is indeed linked to subsequent cardiovascular disease (Zanstra and Johnson, 2011).

Still, even if such studies eventually prove compelling, the concern about the possible role of unmeasured confounders ever looms over the temptation to claim that CVR itself is directly responsible for the associated events (Carroll, 2011). The cardiovascular diseases that are more likely to occur in individuals with high CVR might be caused by other complex factors that are difficult to fully control for such as diet, drug intake, physical activity, sleep quality, or as yet unknown factors influencing disease progression. Because effect sizes are small, these issues cannot be addressed by incremental improvements in the ability to control for these confounders. Thus, the hypothesis that CVR itself is damaging to the cardiovascular system will await confirmation until intervention methods are devised to specifically reduce CVR to stress. Then clinical trials will show whether CVR-targeted therapies do indeed influence the development of cardiovascular disease. For example, it will soon be possible to test whether patients with heart rate and BP under artificial control (perhaps recovering heart surgery patients with pacemakers and implanted variable rate drug pumps containing BP reducing medication) fare better if their CVR is effectively

dampened whenever the patient self-reports psychosocial stress.

Laboratory Research on CVR

Typical Procedural Timeline

The typical features of common CVR studies include baseline measures, stressor presentation, and recovery periods.

First, participants are instrumented with a device that measures BP and/or heart rate and then sit through baseline period usually between 5 and 30 min. Cardiovascular measurements are taken throughout, and the mean of these represents the resting measure.

Next, a stressor is then presented, typically for 2–5 min, although longer tasks have been used. More will be said about how stressors are chosen in a later section. Cardiovascular measurements are usually taken at the end of the stressor period, and the average represents the 'task' level. Reactivity is usually defined as the difference between the mean baseline value and the mean task value. More sophisticated representations are also used, in which the baseline is controlled statistically, to account for individual differences in resting levels.

Finally, recovery data may be collected. A post-stress rest period provides a way of evaluating return of the physiological parameter from the stress-induced levels to prestress levels. Cardiovascular measurements are taken during this period. Recovery is more difficult to measure than reactivity; area under the curve is often used as the measure. See Linden et al. (1997) for a review of the various reactivity measures.

The Laboratory Milieu

The laboratory does not necessarily represent a neutral test venue. Subjects come in with a range of expectation, hostility, fear, anxiety, and other characteristics that may influence their baseline and possibly task levels. Carefully controlling as much of this otherwise unexplained error will result in cleaner data, reducing the likelihood of Type II error. It is important that the experimenter be aware of these issues, because it is crucial that his or her demeanor, tone, and other verbal and nonverbal behaviors be carefully controlled between subjects. Because this level of detail may begin to slip over time, quality control checks may be necessary to ensure consistency throughout the study period.

Selection of a Stressful Challenge

Several factors must be taken into account when deciding on a task.

Conceptuality

Does the task conceptually represent the situation being studied, in terms of both psychological and physiological aspects?

Psychometric Properties

Is the task well supported in terms of its reliability, and validity? The results depend on the selection of the task. Make sure there is evidence that the task manipulates what it is supposed to manipulate (e.g., Is the commonly used serial subtraction task manipulating anxiety or active coping?).

Individual Tasks/Challenges

The question of what precisely is being manipulated by many of the common tasks remains highly controversial. They are meant to arouse stress, and undoubtedly they do, but stress is a complex construct, and what specific aspect of 'stress' is aroused by, e.g., public speaking versus the Stroop task, is unclear. Alternatively, it is important to remember that although two tasks may have very different 'phenotypes,' they may still share a conceptual basis. Thus, the mirror star-tracing task does not share any obvious characteristics with, e.g., the Stroop task; however, to the extent that the two tasks involve a manipulation of frustration, they may be said to represent two measures of a single construct.

The Cold Pressor

Historically, the cold pressor was the first task used in a published study of CVR (Hines and Brown, 1932), and was then used in virtually every such study until the late 1950s. The justification for its selection was simply the authors' need for a simple, noninvasive way to elevate BP that could be used in the physician's office (they were trying to develop a diagnostic test for predicting hypertension). It is not clear, however, precisely which dimension of stress is being represented.

Mental Arithmetic and Serial Subtraction

Although the procedures vary from study to study, mental arithmetic is the most commonly used mental stressor in studies of cardiovascular psychophysiology. Typically, the subject is told that he or she will be given a large number and asked to subtract backward from that number aloud, often by 13 s. The task may be used to represent harassment, when the experimenter interrupts to tell the subject that she has made an error and must begin again.

The Stroop Color-Word Test and the Mirror Star-Tracing Procedure

These are two examples of brief cognitive tasks that are commonly used in reactivity studies. In the *Stroop Color-Word Test*, subjects are presented with a list of words that are the names of colors; the words are printed in ink of a different color from the color name. Subjects are asked to name the color of the ink for each word, rather than read the color that is spelled out. The discrepancy between the ink color and the color name creates interference, which is stressful for the subject. In the *mirror star-tracing procedure*, subjects are asked to trace the outline of a star while looking at its reversed image o in a mirror rather than looking directly.

Social Interaction Tasks

A relatively simple social interaction that can be modeled in the laboratory is public speaking, which is stressful for many people. The speech should last at least 5 min. The participant then proceeds to deliver the speech.

The Trier Social Stress Test (TSST) was developed (Kirschbaum et al., 1993) and is believed to induce stress responses by inducing perception of a social-evaluative threat and uncontrollability (Dickerson and Kemeny, 2004). In the first task, subjects are given 10 min to prepare a speech about why they should be hired for a job; they then deliver the 5-minute speech, which they are told is being recorded and judged based on speech and body language. If subjects pause for more than 10 s during the speech, they are told "you still have time, please continue"; after a total of 20 s panel members will begin asking questions. Immediately following this task, subjects are instructed to perform oral serial subtraction (counting backward from 1687 in 13 s) in front of the panel for 5 min, starting over each time they make an error. At the end of the 20-minute test, subjects are debriefed and informed that no taping or evaluation occurred.

Distress/Anger Recall

The methods described so far have used some means of provoking feelings of stress, anger, anxiety, frustration, and so on. A different strategy, however, is to take an idiopathic approach in which the subject describes events and feelings concerning a past stressful situation. The first report of an 'anger-recall' task was provided in a study by Ironson et al. (1992), in which she had subjects recall life events that had greatly angered them, as a means of recreating a state of anger in the laboratory. An advantage to this stressor is that it does not depend on the subject's reaction to an artificial task, but allows the experimenter to measure physiological changes in response to a stressor that is real and important for each subject.

Poststress Recovery Phase

Researchers have tended to focus on the cardiovascular changes that occur during exposure to a stressor, and therefore many studies of cardiovascular psychophysiology end after the task is presented. However, it is often useful to have the subject sit for a second rest period after the task phase, as recovery of the prestress baseline may yield valuable data. The CVR paradigm has been extended in recent years because data suggest the return to the prestress resting level may also have a role in predicting cardiovascular disease. In a meta-analysis, Hocking-Schuler and O'Brien (1997) reported that persons at high risk for hypertension showed poorer BP recovery than low-risk persons, and several studies have shown that recovery of BP following exposure to a pressor stimulus such as the cold pressor test is slower in hypertensives than in normotensives (Hines and Brown, 1936; Hocking-Schuler and O'Brien, 1997). In addition, we and others have shown that children of hypertensive parents have poorer BP recovery than children of normotensives (Gerin and Pickering, 1995). To date, four studies have prospectively investigated the relationship between delayed BP recovery from psychological stressors in the laboratory and the development of hypertension (Borghi et al., 1986; Steptoe and Marmot, 2005; Stewart and France, 2001; Treiber et al., 2001). Each of these studies found that poor BP recovery following mental stress predicted future BP levels; two found that recovery had greater predictive power than CVR (Borghi et al., 1986; Steptoe and Marmot, 2005).

General Methodological Issues

Frequency of Measurements

The frequency of measurement varies with the specific measurement. Thus, heart rate can be measured at smaller intervals than BP (when using an arm cuff), as each BP measurement takes at least a minute and perhaps more. The general concern is the reliability of the measure. Thus, one reason for the importance of the interval size is that it determines the number of measurements that can be taken within a given phase of the study. In a 1993 paper, Gerin et al. (1993) discussed this topic in depth, using BP measurements as an example, providing a useful discussion in the context of psychophysiological studies. Briefly, basing a measure on the average of several measurements reduces the random error associated with the measure, which increases the reliability of the measure.

Duration of Stressor Exposure

Because BP regulation is almost immediately responsive to one's reactions to the environment, the task duration can be quite brief when BP is the outcome. Three measurements can reasonably be taken during a 5-minute stressor; one at the end of minute 1, at the end of minute 3, and at the end of minute 5. However, there may be advantages of a longer duration task, say, one that goes on for 15 min. In terms of measurement reliability, discussed earlier, a longer duration allows more intermittent measurements to be taken. The TSST is an example of a stressor of longer duration than most laboratory stressors.

Probe Measures

Throughout the session, it may be useful to take measures that will help to interpret the physiological outcomes. For example, a simple measure involves asking the subject a question, such as, "How angry do you feel at this moment?" and having the subject use an interval-level scale (for example, 1 equals 'not at all,' 7 equals 'extremely').

Type I Error

Psychophysiological experiments provide many opportunities to take advantage of chance. Every additional outcome measure included, for which there is no strong, a priori hypothesis based on the literature and relevant pilot data, adds to the experimentwise error rate. For example, BP is often measured as both systolic and diastolic pressure, with each outcome treated in a separate analysis; however, rarely are hypotheses provided for when each measure, on its own, should be affected by the stressor; thus, the Type I error rate in that instance is almost double what is reported.

Individual Difference Characteristics

A number of demographic, constitutional, and personality factors that are associated with hypertension and coronary heart disease have also been shown to influence CVR, and should be considered for inclusion as covariates when

conducting CVR studies. An exhaustive list of these is beyond the scope of this article; however, it is worth mentioning that family history of hypertension affects reactivity although both positive (Lawler et al., 1998) and negative (Muldoon et al., 1993) findings have been reported. A meta-analysis of 48 studies (Pierce et al., 2005) found that individuals with a positive family history showed increased CVR to a wider range of stressors compared with those without a family history, but not a larger magnitude of reactivity overall.

Ethnic background has also been studied as a determinant of CVR. The majority of studies that have examined black–white differences to standard laboratory stressors such as mental arithmetic have shown that both black children and black adults exhibit larger cardiovascular responses to these stressors (Anderson, 1989; Brondolo et al., 2003). Based on the hypothesis that exposure to racism may partially explain differences in hypertension (e.g., Krieger, 1990), a number of CVR studies have used a stressor that involves racial discrimination. The results have been inconclusive, with some studies showing blacks having greater reactivity to the stressor, and other studies showing null results (Brondolo et al., 2003; Harrell et al., 2003; Lepore et al., 2006).

Gender. Studies reporting gender comparisons have tended to show that men exhibit greater systolic BP reactivity to stress, while women tend to have greater heart rate responses (Allen et al., 1993; Kudielka et al., 2004; Stoney et al., 1987). Although few studies of menopausal status have been conduced, the data that do exist suggest that postmenopausal women tend to have greater heart rate and systolic BP reactivity than premenopausal women (Bairey Merz et al., 1998; Saab et al., 1989; see Rose et al., 2004; for an exception).

Socioeconomic Status (SES). There is evidence indicating that higher SES, reflected by higher educational attainment or occupational grade, is associated with increased CVR to mental stress (Carroll et al., 1997; Musante et al., 2000; Rose et al., 2004). This relationship is complex, however, with a number of mediators and moderators of the SES–CVR association having been reported (e.g., Armstead et al., 1994; Chen and Matthews, 2001; Merritt et al., 2004).

Summary and Conclusion

CVR continues to be a dominant biopsychosocial approach to understanding the effects of environmental stressors as they affect cardiovascular disease. The greater challenge, however, is to design studies that us to understand the roles that reactivity and recovery models may play in the pathogenic chain leading to hypertension and heart disease.

The reactivity model has evolved greatly over the past three decades. Researchers are investigating processes never envisioned by the original theorists, with a focus on those that appear to be implicated in the pathogenicity that causes cardiac events, including platelet aggregation and endothelial dysfunction. In addition, the changes in these many parameters, as a function of mental stress, are also being examined with indicators of dysregulation in other biological systems, including immune function and the hypothalamic pituitary axis. The behavioral genetics of acute cardiovascular responses is being elaborated, and sophisticated techniques employed to identify the genes implicated in the observed individual differences in cardiovascular reactivity, and the subsequent cardiac outcomes.

Even with its 80-year history of study, the role of CVR as a cause of cardiovascular disease remains controversial, and more study is needed before strong conclusions can be drawn. The ultimate question, of course, is whether or not intervening to attenuate CVR will reduce the likelihood of developing hypertension and coronary heart disease.

Abstract

Fernando Henrique Cardoso is one of the most prominent Latin American intellectuals, since both his sociological contributions in topics such as social change, democracy, and modernization and his recognition as political leader, reaching the presidency of Brazil. His ideas on dependency theory gave him nevertheless an international recognition. This article, firstly, presents a reconstruction of his lifetime in terms of his academic and political actions. It firstly examines his education and main sociological ideas, revising his main works. Secondly, it offers a summarized picture of theory of dependency, its authors and different perspectives, indicating some themes of disagreement. Finally, the article discusses some reasons that could explain the success of Cardoso's ideas and specific points of recent and likely future debate on Cardoso's thinking; specially wondering about what he changed his vision on social change and some controversies in use of classical Marxism.

Introduction

Fernando Henrique Cardoso is one of the most renowned Latin American intellectuals, since both his sociological contributions and his recognition as political leader. Cardoso reached top positions in academic and political fields. He founded and also chaired the *Centro Brasileiro de análise e planejamento* (CEBRAP); he was the president of the International Sociological Association (ISA) as well and developed an extensive career in Brazilian politics as senator and national minister, a calling that included at the end the presidency of the country. Cardoso's influence and legacy is very important, not only in Latin America but also worldwide, in topics such as social change, democracy, and modernization. Though, his ideas on dependency theory gave him an international recognition.

Cardoso was born in Rio de Janeiro in 1931. He was the eldest of three children in a family with military tradition. His paternal relatives had strong political links and had participated in previous revolts and revolutions. However, his father became a lawyer when he retired from the army and was elected a federal deputy defending combinatory leftist, liberal, and nationalist viewpoints. When the son entered Secondary School, the family moved from the cosmopolitan city of Rio to the then more bucolic atmosphere of São Paulo. This city was at that moment changing from a rural alike place to a developed urban area, a process driven by the modernization of local elites. It would become very rapidly the center of industrialization of Brazil and one of the biggest metropolises in the world, which is today. This was the location where the teenager Cardoso watched profound social transformations and processed the eclectic ideas he absorbed everyday at home and school (Kahl, 1976: 130–131).

Brazil had not at the 1940s a long-term academic tradition; universities were founded lately. This country was a case in which sociology institutionalized very late but professionalization of the discipline happened relatively promptly, in contrast with Argentina, for instance, in which it was the opposite (Pereyra, 2010). Teaching of sociology at the universities started in the 1930s at the level of degree studies and in 1950s at the postgraduate level (Porto and Dwyer, 2010). Nevertheless, sociology was not absolutely a novel field in Brazil before 1930. It was included in secondary teaching from the 1920s to 1942 (certainly from a strong positivist standpoint), and particularly São Paulo's schools openly welcomed that disciplinary knowledge.

One key institution was the University of São Paulo (USP). It was established in 1934 on the basis of the *Escola Livre de Sociologia e Política de São Paulo* (Free School of Sociology and Political Science), created during the previous year by donors from local emerging business class. It was clearly a step in the path of modernizing the state and educational system of Brazil. The USP rapidly combined several independent research and higher educational institutions and hired professors coming from France, Italy, Spain, Germany, and other European countries. The *Escola Livre* remained attached to the university but kept some intellectual and administrative autonomy. This led to a successful institutional development. The USP became a central academic actor in the country. It created an intellectual revolution, especially in social sciences field; meanwhile, the *Escola* organized postgraduate programs and strongly contributed in the institutionalization of sociology in the region (Limongi, 1995). Cardoso's education was plainly marked up by the experience of his studies at the USP.

Education, Traditions, and Early Training

Fernando H. Cardoso registered in 1949 as a university student at the Social Sciences Department. Curiously, he first applied for entering into Legal Studies Area (probably following a family mandatory) but he failed a test in Latin. This examination's adverse result changed thus all his vocational career and future. After changing option, he witnessed in the university an interesting debate about the nature of sociology and the need of renovating teaching and research. While the sociology courses at the *Escola Livre* followed the empirical model (mainly tutored by the American sociologist, Donald Pierson), the teaching of sociology at the USP was more inspired by French intellectual tradition. Cardoso was immersed in the discussion and learned from both sides (Kahl, 1976; Limongi, 1995).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61318-1

Two decisive names who taught at the USP influenced Cardoso's student ideas: Roger Bastide and Florestán Fernándes. The first was a French sociologist (1898–1974) who specialized in literature, social history, and anthropology, giving special attention to religion and conscience. The second was a local professor (1920–95) who was renewing sociological tradition in Brazil. Although Cardoso was just a decade younger than Fernándes, the former found an inspirational mentor in the latter. Cardoso became an obedient disciple, learning from the Fernándes' lessons different authors from German sociological tradition (Weber, Marx, Mannheim), reflecting upon the relationship between economy and culture, and discussing the impact of social structure in social and individual actions. But these continental and classical theories were jointly studied with an empirical emphasis inspired by aforementioned Pierson's ideas (Arruda, 1995). Cardoso always remarked that Fernándes was very influential in modeling his own sociological framework (Kahl, 1976: 130). Their careers separated (not openly, certainly) much later, nevertheless, since they followed diverse political ways in terms of political preferences and party participation. Probably, diverse social backgrounds (a deprived home in Fernándes' case and a prosperous middle-class childhood in Cardoso's one) could partially explain the path but this is not a sufficient explicative.

While still a student Cardoso took part in an intellectual debate, which was probably foundational to the establishment of modern sociology in Brazil. It was the topic coined as the 'Negro question,' in which local intellectuals from diverse disciplines tried to understand the social integration of Brazilian people with African origin and the possible emerging of a unique national identity. That idea became a well-funded UNESCO project on the position of Negroes in Brazil. The aim of the sponsors was to prove that Brazilian society was an unproblematic melting pot. Fernándes was interested in participating in the research because he wanted to show the wrongness of that idea. So, he invited Cardoso to join himself, Bastide and all the investigative staff, so the advanced students collaborated in fieldwork and data analysis (Kahl, 1976: 131; Platt, 2010a). The voluminous collected material was the basis for the writings from professors and a whole cohort of young sociology students at the USP, including Cardoso as likely the most active of them.

Cardoso began lecturing both economics and sociology at the USP even before graduating. He received a degree in sociology from the same university in 1952 and a master degree one year later when he was appointed as teaching assistant, position held until 1961 (Kahl, 1976: 131). Cardoso's main research interests at that time were to deal with the issue of slavery and the situation of *Negros* in society. That question connected empirical studies with the national issue. Consequently, he realized gradually that their status was based on their class position within a capitalist system.

His first book on this research was published jointly with Octavio Ianni (1960) *Cór e mobilidade social em Florianópolis* (Race and social mobility in Florianopolis), in which the authors specially studied social obstacles that stopped and closured social change and upright mobility of Negros in certain regions of Brazil, scrutinizing slavery and salary regimes in economies oriented both for internal and external markets. This first book clearly displayed the legacy he acknowledged from Bastide and Fernándes, but also from Antonio Cándido, another key figure of sociology at the USP (Jackson, 2008). The second publication was Cardoso's doctoral dissertation (1962), *Capitalismo e escravidão no Brasil meridional* (Capitalism and slavery in Southern Brazil); which was supervised by Fernándes himself. Both works showed that his research method was definitely established: a combination of ethnographic field strategies (interviews and direct observation) and historical data analysis, all oriented by a vision on society's plenty of structuralism. At that point, Cardoso was convinced that his sociology could connect the singularity of Brazilian society, Marxist debate, and national politics.

In 1961, he was promoted to full professor and organized a research unit at the USP aimed to study problems on industrial sociology, taking ideas from the Laboratory of Industrial Sociology founded by Alain Touraine in Paris. Cardoso visited this city for some months, changing ideas and experiences with Touraine, Raymond Aron, and Michael Crozier (Platt, 2010a). After returning home, the political situation of Brazil troubled. In 1964, there was a military coup. The new administration blacklisted him from teaching and he had to hide initially and later, when family connections were insufficient to keep him safe, he fled to Argentina. After few weeks, he moved once again to Santiago de Chile, having been called for a new and promising intellectual project.

Cardoso was hired by the *Instituto Latinoamericano de Planificación Económica y Social* (ILPES, Latin American Institute for Economic and Social Planning), which was a research body recently created by the UNESCO in association with the Economic Commission for Latin America (CEPAL, as usually known by its Spanish acronym). When established, the ILPES was conceived as an organization oriented to train bureaucracy all over Latin America, strengthening its capacity for both the formulation and application of finance plans and the development of investment policies. That was the context of the so-called Alliance for Progress pushed up by Kennedy administration. But the agenda changed since a new and different intellectual project emerged (Gabay, 2010).

Chile was a crucial pathway in the production of social knowledge at that time. Not only CEPAL had headquarters in Santiago, also the Latin American School of Social Sciences (FLACSO) had been founded in that city by UNESCO. Those institutions contributed all together to both the reinforcement of Latin American identity and the institutionalization of local social sciences (Beigel, 2013). Cardoso found in that country a brainstorming atmosphere: local minds, Latin American scholars, enduring contacts with Paris (that meant keeping links with Touraine), and a group of Brazilian intellectuals who also were pushed into exile (Celso Furtado, Francisco Weffort, Theotonio Dos Santos, Vania Bambirra, among others), with which would redefine the question of national development and social change in the region.

CEPAL was one of the five regional commissions of the United Nations. It was founded in 1948 for the purposes of contributing to the economic and social development of Latin America and coordinating international actions. Under the strong leadership of Raúl Prebish, it profoundly influenced Latin American thought, applying an original approach in the analysis of development: the center–peripheral model

(Dosman, 2008; Bielschowsky, 2009). Cardoso realized very promptly that the theory of development coined by CEPAL should be questioned since the explanation was based excessively in economic factors. After studying the case of entrepreneurs in Argentina and Brazil, Cardoso started understanding the role of elites in stopping or blocking development in peripheral areas, giving special attention to culture and ideological factors (Cardoso, 1971). With his Chilean colleague, Enzo Faletto, he opened a reflection upon a new idea on social change. It would be the internationally famous theory of dependency, which responded to the then existing sociological and economic theories that were unsatisfactory explanations about development in Latin America.

Theory of Dependency and International Actions

After circulating for some time in manuscript and discussed massively in classes and seminaries in Santiago, Rio, and Buenos Aires, their work was finally published as *Dependencia y Desarrollo en America Latina* (1969a, Dependency and Development in Latin America), having a countless impact. The same year, Cardoso sent to press many drafts of his works during his period in Santiago, in which the empirical and hypothetical framework of the new theory could be found (1969b). This theoretical project was not merely an isolated effort since almost the entire research staff at ILPES had been working in related fields. The academic audience understood and was ready to discuss the issue; Cardoso and Faletto were not original but they put the debate in plain words, offering an easy interpretative scheme. The theory was a boom since the field was disenchanted by preceding developmental theories. They were shifting to leftish positions. This intellectual corpus was read in a time that academic agenda was redefining the role, challenges, and commitments of Latin American intellectuals and both anti-colonial and anti-imperialist discourses were emerging (Gilman, 2003).

Dependency theory offered therefore a new sociological definition of underdevelopment combining the analysis of society with economy and politics. It advocated an inward looking approach to development, in contrast with previous CEPAL ideas. Cardoso and Faletto claimed for an integrative and global analysis of social change, focusing both on the singularity of national historical conditions and the goals and interests that oriented social conflict among social groups. Thus, they demanded for a perspective based on the idea of 'historic and social process,' a way of understanding social domination in combinatory terms of politics, social structure, and culture (Cardoso and Faletto, 1969).

After *Dependency and Development* was printed, the debate on this issue expanded. It became the core of intellectual arena and hundreds of papers, chapters, and books were published. Gradually, discussion moved from official agencies to universities and academic meetings, mainly sponsored by the Latin American Sociological Association. In 1977, Cardoso and Faletto needed to rewrite some ideas in response to misunderstandings and confusions and the way that, according to the authors, their colleagues established wrongly a discussion on the idea of dependency. That resulted in a kind of brief sequel of the original book, the *postscriptum of Dependency and development*. Basically, diverse authors have discussed on dependency in two different ways. Some (Vania Bambirra and Ruy Mauro Marini, among others) affirmed that it was entirely a theoretical framework and dependency was a key category of capitalism in underdevelopment societies since it was thought in terms of mode of production. Others, led by Cardoso, stated that the so-called theory of dependency was not exactly an articulated system of ideas but an intellectual approach to a distinctive problem; in other words, a perspective of analysis. Thus, it aimed to design an analytical study on a particular articulation between social classes, economy, and state.

After exiling in Chile, Cardoso returned to Brazil in 1968 and passed an examination that allowed him to teach at the USP. However, the military government put his political rights off and his university contract was canceled. In contrast with his earlier similar experience, he did not move. Although things were not quite calm, he stayed in São Paulo, with the conviction of improving life in Brazil. In conjunction with other lecturers and researchers in the same conditions, Cardoso founded in 1969 a new body which would become his home during the following decade. It was the CEBRAP (Brazilian Centre for Analysis and Planning). It was a private organization sharing a common history of similar institutional experiences in the region during 1970s and early 1980s. Such bodies expanded in Argentina, Chile, and Uruguay; they aimed to gain autonomy from dictatorial political intervention in those countries. Soon, the CEBRAP reached a significant academic prestige. It was well funded by Ford Foundation, had consultancy contracts, and even received resources from national and federal official agencies with which could build up a steady interaction. In some way, it was a model to follow by regional bodies alike: how to get independency and collect money for doing research; its institutional visibility helped its actions to have better impact in local culture and politics (Brunner and Barrios, 1987). Researching at the CEBRAP, Cardoso reinforced his reputation as a critic of the military regime and an advocate of a peaceful transition to democracy, but also established an important network of political and academic links both nationally and globally.

These connections implied an active participation at international bodies. So, Cardoso occupied important positions in the ISA. After holding a vice-presidency in the period 1978–82, he was elected president for the following four-year term. At the moment of the election he was not only a key man within the field but also a well-known name to the general public in Brazil and abroad. His job at the ISA was regarded by his contributions to the development of sociology in peripheral areas; it should remember that 1982 and 1986 ISA congresses were held in Mexico City and New Delhi, respectively; which was a fact of the ISA decision to first time move sociological discussion away from Europe and the US (Platt, 2010a).

It was clear in his agenda that sociology had to follow scientific tradition but it was not a reason for abandoning commitment and ethical values (like justice and fraternity) that orient the actions of sociologists (Cardoso, 1986). His political skills were very helpful to be a good institutional leader, although he often exercised his functions at a distance. Cardoso's successful career at the ISA could be understood tracing back his earlier contacts with UNESCO, which also refreshed the productive French–Brazilian academic

connection. There could have been a Touraine-related trail in some way, but Platt (2010b) suggests some methodological caution in following such trails; the study of those connections should be developed, though.

Political Career

Cardoso was active in local politics since the late 1970s. He started his political career when he was put forward as a candidate for the Senate in 1978. He failed this first attempt. He was elected twice as senator from Sao Paulo, nevertheless, from 1983 to 1992. During his job in the national congress, he was one of cofounders of the centre-left Brazilian Social Democratic Party. In 1992, after President Fernando Collor de Mello was impeached for corruption and was replaced by Itamar Franco, Cardoso was called for duty to become successively Foreign Affairs and Finance minister. Therefore, he had to face two definitive challenges: inflation and social disturbances. After establishing some consensus with the opposition and labor leader Luiz Inácio da Silva (nicknamed Lula), Cardoso coordinated with firm determination the application of a sensible and simple financial plan, named *Plano Real*. The plan resulted at last, stabilizing prices and ordering the economic situation. It was widely credited for bringing Brazil out of economic chaos (Cardoso, 2006).

To take advantage of his political prestige and recent fame of 'storm tamer,' Cardoso entered later the race for and won the presidency in 1994. It was clear that the support of the national business community was crucial for the decisive victory. During his administration, he emphasized further economic reform, including privatization and increased foreign investment, as well as funding for education and social services. In 1997 voters approved an amendment to the constitution that allowed the president to hold consecutive terms and one year later Cardoso became the first Brazilian president to be reelected for a second four-year period. By that time, however, Brazil was facing severe financial problems, and his administration was forced to pursue an austerity plan, which included spending cuts and tax increases, to reduce the budget deficit and to secure international loans.

Probably, one of Fernando Henrique Cardoso's greatest triumphs at presidency was his successful policy to reduce AIDS rates in Brazil. His time in government is also acknowledged by his challenge to pharmaceutical sector and the decision to promote generic cheap drugs in order to combat illness in his country. Barred constitutionally from seeking a third consecutive term, Cardoso left office in 2003, leaving the post to the *Partido dos Trabalhadores* (PT, Labour Party) under the strong leadership of Lula, which is still in power. When delivering the presidential scepter or when hanging his sash up, Cardoso could have recalled that Florestán Fernándes had been one of the main and well-harked officials of the PT.

In addition to the University of São Paulo, of which he is emeritus professor, Cardoso has taught at a vast number of universities: Santiago, Chile, California (Stanford and Berkeley), Cambridge, Paris-Nanterre, the École des Hautes Études en Sciences Sociales, and the Collège de France. From 2003 to 2007, he was professor at the Thomas J. Watson Jr. Institute for International Studies, at Brown University in the United States. Along his career, Cardoso has as well received honorary doctorates from more than 20 universities; he is also an honorary overseas member of the American Academy of Arts and Sciences. He was elected twice (2005 and 2008) as one of the hundred major public intellectuals of the world in a survey conducted by the renowned scholarly periodicals *Prospect* and *Foreign Policy*. Nowadays, he has an active academic and political agenda. He enthusiastically lectures at conferences on topics from economics to AIDS. He also participates at different forums related with international affairs and developmental policies and takes part in different boards of cultural or academic organizations. His intellectual production is really wide. Besides numerous journal articles published in diverse countries, a complete set of his pronouncements and speeches as president of Brazil was published in 16 volumes by the Presidency of the Republic (2002). In *The Accidental President of Brazil* (2006), he presented a good summary of both the political events and a personal insight into the sociology of Brazil.

Debate and Controversies

What remain unclear are the precise reasons of Cardoso's intellectual success. Kahl (1976), Goertzel (1999), and Platt (2010a) suggest that he could define a key question and was always able to keep it at the center of his intellectual worries, offering a sociological explanation historically situated and giving up any pretention to build up a general theory. Kahl (1976: 186–187) additionally advocates that the sociological impact of Cardoso's work is so shocking since his thinking did give out an answer that could fill the gap and bias of existing theories such as functionalism, Marxism, and modernization theory in the explanation of social change in Latin America. A further point to be well-thought out is that dependency theory emerged in a time when an enthusiastic audience was waiting for revelation: the singularity of Latin America in terms of culture and economy should be explained by a singular not imported theory. Formulae from center had evidently failed so it was welcoming a new recipe with local ingredients and flavors. Cardoso was the major chef at that occasion.

Moreover, a debate on Cardoso's ideas was emerging, which could lead to a promising research agenda. Some academic voices questioned Cardoso's policies when he was at ministerial or presidential power. Many accused him of betrayal since his governmental policies seemed to be far away from his previous ideas on Marxism and dependency. This could be considered only a local dispute between Labour and Social Democracy in Brazil. But in fact it is more complex since the discussion could be traced back to the 1970s when the polemics on the nature of dependency peaked. For example, one key author of dependency theory, Theotonio dos Santos, questioned Cardoso in 2010 via a public letter in which the former president was blamed to have applied neoliberal policies and to have blocked both a real industrialization process and the empowerment of working class; such actions are said to be distant from left legacy. It is important to say that dos Santos affirmed Cardoso's shift had already begun 30 years before when they argued each other on the interpretation on social change in the region.

The key point to take into account is whether Cardoso changed or not his sociological mind along his academic and political career. In the first scenario, Cardoso dramatically changed his vision on society. Cardoso had a strong compromise with revolutionary changes in the past and later became a neoliberal politician. Nevertheless, the second picture showed a more invariable intellectual outlook in Cardoso's actions. One should reflect upon the nature of Cardoso's dependency approach, though.

One may reason that his ideas made a rupture with the classical theory of modernization. In that sense, the destiny of Latin America should follow a different and alternative path that the more advanced societies, which meant that the entire idea of development is false and wrong. In that reasoning, the only way to change dependence situation was a social revolution. On the contrary, one might also think that the theory of dependency is a critique of developmental theories but also a continuation; since dependency could be assumed as one singular obstacle to the progress of peripheral societies. Thus, when countries could solve that problem they can establish modern economic and political institutions.

Cardoso seemed to have not renewed much of his ideas since one can observe, he has never abandoned his ideas on democracy and political participation. *Dependency and development* did not question democratic institutions. In a competition between liberal and populist traditions on the idea of democracy, Cardoso seems to belong to the first one and opposed to the second. One could see as well that Cardoso had a liberal standpoint from his first writings; he believed all nations follow the same civilizatory process, although found different obstacles and blockages. Dependency was one that distinguished Latin American countries from other national experiences. Hence, Cardoso was more familiar to Gino Germani's vision (1979) on modernization than it was considered before.

The issue of the use of Marx seems to be crucial. Here, Cardoso's ideas are likely related with the interaction between liberalism and Marxism, an intellectual project raised at the same time by names such as Anthony Giddens and Jürgen Habermas. Cardoso's thinking looks like to admit an international use of Marx's ideas in contrast with the other side of dependency theorists who aimed to find a Latin American Marxist approach. Cardoso's thinking could be as well placed in the context of a new interpretation on Marxism and the redefinition of democracy in Latin America during the early 1980s, just the time Cardoso himself was beginning his political career. The research agenda shifted then from development and dependency to an examination of political, economic, and cultural conditions that promoted democracy in the region (Lechner, 1988; Pereyra, 2010: 219).

But the main theme tune of debate is the relationship between social classes and social change. While classical Marxism emphasizes the role of proletariat in the revolutionary process, Cardoso's ideas seems to run down such actions from the masses, which was the base of dos Santos' critique. Contrarily, Cardoso's theory of dependency appears to be appropriate to study social elites since, according to him, would be the group which promotes social change by moving dependency conditions and redefining state autonomy. That stress on both the autonomy of upper class and the importance of cultural and ideological factors was an oddity in Classical Marxism but was not so strange in the region where Gramscian ideas became popular. It is necessary to recall the importance of Gramsci in Brazil, as well in Argentina. But this vision could also help in understanding why Brazilian bourgeoisie have enthusiastically read Cardoso's ideas and backed his leadership.

The question is open and debate will continue. Although, it complicates even more if you add to the scene the political parties' competition within Brazilian context and the disputants' social capitals. To sum up, Cardoso' ideas are fecund and creative, giving an original vision of social change in Latin America and the conditions that could block development and democracy in those countries, rethinking the idea of social structure and modernity, served with liberalism, spiced with Marxism, and well seasoned with classical sociology, though.

Career Development: Multilevel Perspective

Yehuda Baruch, University of Southampton, Southampton, UK

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by A.B. Weinert, volume 3, pp. 1471–1476, © 2001, Elsevier Ltd.

Abstract

In this article, I discuss careers from various perspectives, in particular, as an individual phenomenon, organizational system, and society in general. I discuss the changing nature of careers and how they became more dynamic, in line with the wider business environment. Exploring labor markets and careers as an ecosystem I explore factors influencing careers and the nature of career planning and management. I then move to career outcomes, again, at the three level of analysis: individual outcomes, organizational outcomes, and national outcomes. In terms of practical management of careers, I list the various practice organizations that may employ to deal with career planning and management and how they can be integrated. I refer to issues that associate careers with other elements of human resource management, such as global careers, labor markets, work–life balance, and the issue of diversity. Finally, I present a view of the shape of the things to come in the future of careers.

Careers: Individual and Organizational Perspectives

Career is "an evolving sequence of a person's work experience over time" (Arthur et al., 1989) or "a process of development by employee along a path of experience and roles in one or more organizations" (Baruch and Rosenstein, 1992). Career is a salient element in peoples' working life, hence life in general, as work life and private life are interwoven to a high degree. Careers are managed simultaneously by individuals and their employers, and take place in increasingly dynamic (Hall, 2002) and global labor markets (Tams and Arthur, 2007). Already early seminal works highlighted the micro- and macroframes of references for studying careers. One example is by Schein (1978), who combined both individual and organizational perspectives. Career studies originating from the individual perspective tend to deal with career choice (most notably Holland, 1959), and career stages or life cycles (Super, 1957). From organizational career system perspective, career systems deal with identifying, planning, developing, and managing people throughout their employment within the organization.

A distinction typically made within career studies is between individual-focused and organizational/cultural-focused perspectives. I argue that a better approach would realize the complementariness between the two perspectives. Rather than distinction, there is certain convergence in the literature, pointing out that to reach comprehensive understanding of careers, it is necessary to place it within a wider context. Balancing individual and organizational needs is a critical element needed in career scholarship (Baruch, 2006; Lips-Wiersma and Hall, 2007). Earlier, Herriot and Pemberton (1996) offered a career model that places in its core the prerequisite for a match between individual and organizational needs, wants, and provisions. A system that neglects the fulfillment of such a match will see star performers leaving, lack of ability to attract talent, and overall diminishing commitment and investment. It can be the case for organizations (Kets de Vries and Balazs, 1997), nation (Brain Drain phenomenon – Dickmann and Baruch, 2011), and the wider society (Baruch, 1998).

A broader perspective places career systems within the wider environment – professional, organizational, and cultural realms. These provide the values, norms, and framework for individuals to generate and follow their aspiration, and to benchmark against others (Baruch, 2004a: p. 4).

Yet, there is more to it than individual and organizational relationships. Other actors within the wider systems are significant stakeholders. Governments, unions, professional associations, legal systems, and regulations, all play part in shaping career and career development within and outside organizations. The wider labor market, which is becoming global, can be described as an Ecosystem (Baruch, 2013; Higgins, 2005). Ecosystem is "A system that contains a large number of loosely coupled (interconnected) actors who depend on each other to ensure the overall effectiveness of the system" (Iansiti and Levien, 2004). The career ecosystem operates in a constellation that is not merely economical but also part of social-political phenomenon in a global environment (Gunz et al., 2011). There is a significant 'flow of talent' across organizations, sectors, and nations. People chose to have new, second careers (Baruch and Quick, 2007), to move to a different location or country, either for a limited period or permanently (Carr et al., 2005; Mahroum, 2000). More broadly, people are more open to, or accept the necessity of changes. This goes hand in hand with the individualization of societies, both in western and in eastern societies.

The Changing Nature of Career Systems and Emerging Career Models

New career models emerge, some are revolutionary, and others are evolutionary. These new models developed alongside the traditional model, not replacing it. **Figure 1**, titled traditional alongside multidirectional model, presents what Peiperl and Baruch (1997) termed the postcorporate career, where organizations are changing their philosophy and strategy regarding people management. As a result, their structure and career systems are changing too.

Figure 1 Traditional alongside multidirectional model.

The change in the career's realm is not a singular phenomenon. It should be taken in the perspective of other changes in life generally and management particularly.

Traditional career systems assumed that such treatment will last through the entire career cycle of the employee, whereas contemporary career systems recognize the dynamic and transitional nature of the system (Sullivan, 1999; Baruch, 2004a). Until the 1980s, career structures traditionally focused on advancing in the hierarchy, typically climbing vertical ladders. Even though it was not a reality for many, as the majority hit a career plateau at certain stage, it was still perceived as the ideal type of career – secured, within single organization, with upward mobility. It was in line with conventional perception that a successful career is built out of a set of successive linear moves up the organizational structure, accompanied by increments in formal authority, prestige, and rewards (De Vos and Soens, 2008). The shape of career systems has changed into a boundaryless (Arthur and Rousseau, 1996) and multidirectional career (Baruch, 2004b), where people may hold different career attitudes, such as the protean career (Hall, 1996, 2004). There is certain conceptual ambiguity associated with the new terminology. For example, the protean and boundaryless career concepts overlap significantly, but the protean career concept predominantly focuses on an individual's motives to follow a particular career path, and to take their destination in their own hands, whereas the boundaryless career concept mainly concerns different forms of mobility (Gubler et al., 2013).

Below I list some of the concepts that gained attention in the development of the so-called 'new careers' (Arthur et al., 1999). One caveat to mention is that it is not 'all change,' and as Inkson et al. (2012) argue, the new careers do not necessarily reflect true change, as many, if not most of careers are still more traditional rather than, for example, boundaryless or protean. Current empirical studies (Rodrigues and Guest, 2010; Kattenbach et al., 2013) indicate that there is indeed more rhetoric than actual dynamic in the labor markets, possibly due to the changing economic conditions. In terms of academic perspective, there is a need for a balance in describing new trends and formerly held systems (Baruch, 2006; Lips-Wiersma and Hall, 2007). Another criticism on new career concept is that they tend to reflect individual agency and missing on the context in which careers take place (Grote and Hall, 2013). While there is a higher level of overcoming organizational structural constraints, occupational boundaries still prevent many from going through a significant job change, unless it is a move to managerial role within existing industry, or that the person took a significant retraining and qualifications. Even so, reentering the labor market at a later career stage can prove challenging. In particular, employment for the over 50 years old is fragile, and although people at this stage can perform and contribute, leaving the labor market proved too many times a permanent one-way move.

The Boundaryless Career

A boundaryless career was defined as "a sequence of job opportunities that goes beyond the boundaries of any single employment setting" (Arthur and Rousseau, 1996; DeFillippi and Arthur, 1994). It is possible to capture the boundaryless concept by involving various underlying meanings (Sullivan and Arthur, 2006). Sullivan and Arthur revisited the boundaryless theory by defining varying levels of physical and psychological career mobility between successive employment situations. The posit both physical movement and psychological movement along a continuum, suggesting the concept be

viewed and measured by the degree of boundarylessness as displayed by specific career actors.

The Protean Career

The protean idea (Hall, 1976) suggests that careers can be driven by the values of career actors and directed through personal choice, in contrast to the traditional way, where external agents such as the organization would plan, direct, and monitor careers (Hall, 2004; Hall and Mirvis, 1996). Therefore, in a similar vein to the boundaryless career, the protean career can be conceived along two dimensions: the extent to which the career is driven by values and the extent to which it is self-directed (Briscoe et al., 2006). In a complementary manner, being able to conduct careers according to values and in the direction individuals wish for, the protean career can also be viewed as an unidimensional orientation that reflects or lead to subjective career success (Baruch and Quick, 2007; Baruch et al., 2005).

There are similarities and differences between the protean and boundaryless careers (Briscoe et al., 2006). The protean model is still in a shape of 'becoming' due to the variety of views for the concept and its measurement (Gubler et al., 2013; Baruch, 2014). Protean career is an attitude or orientation of an individual, whereas boundaryless is a depiction of a system where traditional barriers are shattered or reduced, though never cease to exist. People with protean career orientation would find it easier to plan and manage their careers within a boundaryless career environment.

The Postcorporate Career

The concept of the postcorporate career (Peiperl and Baruch 1997) depicts careers that take place outside large organizations. Individuals who leave, voluntarily or involuntarily, individuals unable or unwilling to pursue corporate careers, and can lead career external to the corporate, are the actors and stakeholders in this era. The postcorporate followed from a mass redundancies and 'rightsizing,' where, alongside the large corporation a need emerged for smaller and agile organizations to complement the large corporations.

Rather than looking for merely hierarchical promotion, individuals identify or create opportunities to gain intrinsic and financial rewards. The postcorporate career is still highly contemporary, as major waves of redundancy reoccur, but the postcorporate careers have not become the norm, and fit mostly for professionals, consultants, and managers. The traditional, corporate-bound, career has proved quite robust and has survived through the pressures of competition and rationalization.

The Kaleidoscope Career

The Kaleidoscope Career Model (KCM) (Mainiero and Sullivan, 2006) was developed independently from the protean or boundaryless concepts. Mainiero and Sullivan suggest that like a kaleidoscope mechanism, the KCM depicts how individuals change the pattern of their career by rotating the varied aspects of their lives in order to arrange their relationships and roles through different practices. Changes may be internal or external such as a development in the labor market. People look to reach best fit among work demands, constraints, and opportunities as well as relationships and personal values and norms of behaviors.

The metaphorical mirrors of the career kaleidoscope are the following three parameters or motivators: (1) *authenticity*, in which the individual makes choices that permit being true to oneself; (2) *balance*, whereby the individual strives to reach an equilibrium between work and other facets of life; and (3) *challenge*, a personal need for stimulating work and career advancement. As life span, people search for the best fit that matches the character and context of their life, and the kaleidoscope's parameters shift in response. There is already empirical support for the KCM (August, 2011; Smith-Ruig, 2009).

The Multidirectional Career

The multidirectional career (Baruch, 2004b) is a concept, which manifests a trend in career systems and their meaning and implications for individuals, organizations, and society. The traditional one direction, upward climb in the hierarchy is not a sustainable model any longer. Individuals and organizations are becoming open to wide directions of possibilities to reach meaningful and successful careers. Otherwise they might have a painful 'wake-up call' when the next round of redundancy reaches the individual or the organization faces a shortage of talent (Bedeian and Armenakis, 1998). This is particularly true for people in knowledge and creative industries (Greenhalgh and Rosenblatt, 1984, 2010). Job insecurity can lead not only to negative personal outcomes (Jordan et al., 2002), but also to 'keep one on their toes' and make sure people reinvent and reshape their career, keep updated and competent, ready to move to various directions on the career frontiers.

To sum up the above conceptual developments in the study of careers, it is fair to say that the introduction of new career models and concepts reflects a true change and paints a new landscape of careers where former constraints are dissolved or shattered. In the past, people had the inclination to follow the social norm of commitment, loyalty, and stability, tended to keep with a few workplaces, and preferred to stay with the same organization. Conversely, today's careers frequently go beyond the boundaries of any single organization, and people can change roles and employers, even occupations, without acquiring a negative stigma of job-hopping or unstable professionals (Sullivan and Baruch, 2009). A new psychological contract has been established (Rousseau, 1996; Herriot and Pemberton, 1995), offering altered implications for the wider career landscape. For a sober examination of new and old realities in the area of careers, the reader is directed to Inkson and King (2011).

Factors Influencing Careers and Career Planning and Management

The components forming the *Career Active System Triad* (CAST) are set at three levels of analysis (see **Table 1**): values, approaches, and behaviors (Baruch, 2004a). The basic underlying level of values – the principles, morals, and culture – form

Table 1 The career active system triad – levels presentation

Level	*Individual*	*Organization*
Values	Aspirations	Philosophy (strategy)
Approaches	Attitudes	Policies
Behaviors	Actions	Practices

the roots from which the other levels emerge. The second level comprises of approaches and assumptions that translate those values into the third level, that of action, behavior, and practice. The values convey the aspiration (for individuals) and strategy (for organizations) into the attitudes (for individuals) and policies (for organizations). The third level of actual behaviors is where people will act and apply career-related actions (make a move, retrain, start a new venture), and organizations will utilize managerial practices. The results of such actions are the career outcomes. This is an active system, always in a perpetual motion, responding to both external and internal forces and requirements.

At the organizational system level, organizations develop, explicitly or implicitly, a system wherein the career strategies and practices follow their business strategy (Sonnenfeld and Peiperl, 1988). Organizations realize the need for a clear aligning of HRM strategy and practice with the strategy and practice of the whole business (Holbeche, 1999). The link is relevant not merely for individuals' attitudes and feelings, but also for organizational financial performance (Huselid, 1995; Combs et al., 2006).

The CAST model builds on the theory of planned action of Fishbein and Ajzen (1975) – see **Figure 2**. People's career-related actions are shaped by internal and external factors that influence their work attitudes and work performance, and their deriving intentions lead to behaviors.

Career Outcomes

Individuals thrive to gain career success. The meaning of it is not set in stone. Career success, in terms of outcomes, are typically evaluated or explored in two basic dimensions – objective and subjective. It is never simple to identify what leads to reaching career success. At the individual level, there is a distinction between merit-based factors, such as competence, skills, qualifications, that should be instrumental in people's career progress, and nonrelated issues such as gender, race, age, and other factors that can cause distortion for system that if it is not based on procedural and distributive justice.

A comprehensive meta-analysis by Ng et al. (2005) focuses on the two main dimensions of career outcomes, typically examined in terms of success. The success can be internal (intrinsic) and external (extrinsic). Heslin (2005) has identified avenues for improving the conceptualization and measurement of both objective and subjective career success, including the need for greater sensitivity to the criteria that participants, in different contexts, use to construe and judge their career success. Heslin illustrates that contextual and individual factors are likely to be associated with the relative salience of objective and subjective criteria of career success.

Career outcomes can be not only a source of great life satisfaction and fulfillment, but also a source of stress and frustration. The changing nature of careers means a significant change is the way career is shaped and managed in partnership (or otherwise) between individuals and organizations, within a wider system, regional, national, and global. Arthur et al. (2005) studied career success in a boundaryless career world and argue that typically career research makes inconsistent use of career theory: in particular, it neglects the interdependence of the objective and subjective careers, and 'boundaryless career' issues of inter-organizational mobility and extra-organizational support.

Career success is associated with significant positive outcomes, including happiness, psychological health, and longevity (Kern et al., 2009; Pan and Zhou, 2013). It is typically associated with the social capital theory (Seibert et al., 2001), which is conceptualized in terms of network structure and social resources.

Hall and Chandler (2005) expand our understanding of the relationship between subjective and objective careers, describing a condition under which the subjective career takes on particular salience: when the person feels a sense of calling, a sense of purpose, in his or her career. Indeed there is a clear difference between external success, as can be measured by hierarchy position and income, and internal success, which is about the individual feeling about their achievements.

Career outcomes can be negative, of course: A grim view about the way careers are developing in a growingly individualized society is depicted by Kalleberg (2009). He realized that the landscape of Western careers in a society comprised of individuals who live and suffer from isolation (see also Turkle, 2011).

At the organizational level, successful career planning and management means that they are able to attract, recruit, and retain talent they need. The organization needs to manage a 'talent flow' where new people enter the system, where existing members of staff continuously keep competitive and satisfied,

Figure 2 Fishbein and Ajzen model.

and where individuals' and organizational needs are mutually met. Internal labor markets is one strategy where the organization, at the extreme case, only recruit at the low level, and promotes from within. External labor markets means that the organization is open to recruit at any level from external sources.

Career Outcomes – National Level

At a national level of analysis, career systems can be directed and influenced by strategies and actions of governments and other political and economic bodies. First and foremost, the education system shapes the competence portfolio of a nation. It also helps to shape values of the population, though these are more influenced by the culture, religion, and other relevant factors. Investment in certain areas can generate support for certain industries (for example, high-tech industrial parks). Attractive life condition would form pull factors to attract global talent (Baruch, 1995) whereas countries, which cannot offer such conditions might suffer from the Brain Drain phenomenon, which is typical to global labor markets.

Career Practices and Systems

Sonnenfeld and Peiperl (1988) is a model of career strategies, where organizations adjust their career system to fit their organizational business strategies. In particular by exploring supply flow – do they develop internal talent via internal labor markets, or look outside for talent pool. The other dimension in their model is the assignment flow, where people are assigned with roles, and are promoted according to their individual contribution or their fit for the team/organization. Such strategies are reflected in specific practices that the organizations utilize for the planning and management of careers. Baruch and Peiperl (2000) present an empirical examination of career practices in organizations. Some of these practices are enabling organizational monitoring and control; other practices focus on organizational support and career self-management (Sturges et al., 2010).

Below I list the main career practices available for organizations (based on Baruch, 1999; Baruch and Peiperl, 2000).

Posting (advertising) internal job openings;
Formal education as part of career development;
Performance appraisal as a basis for career planning;
Career counseling by direct manager;
Career counseling by the HRM department;
Lateral moves;
Retirement preparation programs;
Succession planning;
Mentoring;
Common career paths;
Dual ladder (careers offering upward mobility in career tracks other than supervisory or managerial);
Booklets and/or pamphlets on career issues;
Written personal career planning for employees;
Assessment centers;
Development centers;
360° Performance appraisal systems (an evaluation system where employees receive confidential and anonymous feedback from all the people who work with and around them, e.g., peers, managers, etc.);
Career workshops;
Induction/orientation;
Special programs:
for high flyers (a system to identify future leaders based on their capacity to learn and adapt, rather than on the basis of seniority), dual-career couples, and
for ethnic minorities, age, gender, disabled, etc. (EEO);
Creating psychological contracts;
Secondments (temporary transfers of employees from their regular organizations to new assignments).

Integrating Practices into a Coherent System

The above list of practices vary in their applicability and relevance for different kinds of organizations: Factors such as size, sector of operation, location, dependence on human capital, local vs multinational, to name a few, are instrumental for any organization in making a learned choice about which practices to apply. Further, these practices should not be considered in isolation, but rather organizations should engage in developing an integrated system. The system should be designed to answer the needs and requirements of both the individual and the organization. The fit between organizational and individual needs is at the core of Herriot and Pemberton (1996) careers' model. It is also necessary to apply a twofold level of integration: 'internal,' among the variety of practices, and 'external' – integration between the career system and the organizational culture and strategy (Baruch, 1999).

In deciding which practices to use and how to apply them, HRM should consider the following factors or dimensions (Baruch, 2003):

- *Involvement*: from a very low to a very high level of organizational involvement needed while dealing with the specific career practice.
- *Sophistication and complexity*: from very simplistic to highly sophisticated and complex.
- *Strategic orientation*: from very practical, 'tactical,' to very strategic.
- *Developmental focused*: from low to high relevance for developing individuals.
- *Organizational decision making focused*: from low to high relevance for organizational decision-making processes.
- *Innovative*: from very traditional or conventional, to innovative and unorthodox.

Career-Related Issues

Other career-related issues worthy of mentioning here, but mostly covered elsewhere are diversity, global/international HRM, work–life balance, to name a few.

Career and Diversity

The issue of diversity, at the more general level of diversity management, discrimination, and inclusion, is dealt in depth in the article dedicated to these issues – see Gonzalez and Zamanian in this volume. Yet, there are a number of specific diversity-related issues of direct relevance for careers and career management. Looking for talent means that merit and competence should be the leading factors in selecting people for recruitment and later,

for promotion. Yet, in practice, people who do not belong to the majority group tend to suffer from direct and indirect discrimination. For a comprehensive study on the literature on global careers of women see Altman and Shortland (2008). Gender is just one issue. For example, relating to age, Dries et al. (2008) examine whether four different generations (Silent Generation, baby boomers, Generation X, and Generation Y) hold different beliefs about career. The majority of their participants still had rather 'traditional' careers, although younger generations seemed to exhibit larger discrepancies between career preferences and actual career situation.

Careers and Work–Life Balance

Slipovers from work to other facets of life (in particular family) gain high attention within academics (e.g., Jones et al., 2013; Ollier-Malaterre, 2010). Yet, in practice, pressing pressures for highly competitive business environment means that individuals committed to work are being expected to compromise on their work–life balance. Greenhaus and Powell (2003, 2006) discuss the pros and cons of work–life boundaries and propose a theoretical model of work–family enrichment.

Global Careers

Many careers are unfolded across national and other geographical boundaries. There are many types of global careers, and factors such as culture differences play a crucial role in managing careers across borders (Dickmann and Baruch, 2011). In particular, expatriation and repatriation form a growing niche of both career studies and International Human Resource Management (IHRM) literature (Bolino, 2007; Cerdin and Le Pargneux, 2009).

Expatriate assignments can help or hinder advancement of employees who have international experience (Bolino, 2007). Repatriate career success influences an organization's ability to retain its current repatriates and recruit future expatriates. The fit between career and international assignment is likely to affect the success of the assignment at its various stages (Cerdin and Le Pargneux, 2009). Cerdin and Le Pargneux offer a three-stage model: preexpatriation, expatriation, and repatriation to explicate how individuals' career characteristics influence international assignment success during expatriation and repatriation. The literature about global career goes beyond expatriation/repatriation, and the interested reader can find more on it in a number of books (e.g., Dowling et al., 2008; Harzing and Pinnington, 2010) and specific related journals.

The Future of Careers

In the past, wealth was based on physical capabilities, then on capital, primarily land. In the industrial revolution the capital that matter have changed to plant – equipment etc., later to be replaced by financial capital, which was the core key to competitive advantage. These days, the creation of wealth moves to rely on human asset, so individuals look to improve their human capital. In the information age knowledge matters, and, as was always the case, technology – all influence careers and their progress. The shift from agriculture to industry and production generated different career systems. The move to services and now to knowledge management and high reliance on IT generates new professions, and new landscape for careers, in particular virtual careers. People can work from many places – home, office, car; people are connected via fast-pace mechanisms, and updating competencies is a prerequisite for a long-term career success.

One cannot predict the shape of the things to come, but surely future careers will be quite different for the coming generations. The psychological contract will continue to evolve, technology will play a crucial role, and globalization will continue to shape careers.

Readers interested in comprehensive reviews of career studies would find the following useful: Sullivan and Baruch (2009) and Baruch and Bozionelos (2011). For attempts to cover career theory, see the two career handbooks: Arthur et al. (1989) and Gunz and Peiperl (2007).

This article is a revision of the previous edition article by R. Schulz, volume 3, pp. 1476–1479, © 2001, Elsevier Ltd.

Abstract

In this article, the terms caregiving and caregiver burden are defined, basic epidemiological data on the prevalence of caregiving is presented, and the typical caregivers are described. Based on the stress-theoretical approach, caregiving and its potential consequences on different life domains are discussed in more detail. Finally, some future challenges of caregiving are discussed.

Defining Caregiving and Caregiver Burden

Although no general definition on caregiving is available, there is broad agreement that informal caregiving can be described as 'extraordinary care, exceeding the bounds of what is normative or usual in family relationships' (Schulz and Martire, 2004: p. 240). Typically, caregiving is characterized by a substantial expenditure of time, financial resources, and energy, in an extent that exceeds the 'normal' as the care receiver somehow depends on the effort of the caregiver. Close relatives or spouses are often involved in caregiving over longer periods, and they perform it voluntarily, due to a lack of available alternatives or due to the strong wish of the care receiver to stay in the home setting. Caregiving might include displeasing activities, such as helping an incontinent person with bladder management, and can be physically exhausting, e.g., helping a mobility-impaired person getting up. Given unstable health conditions of care recipients, caregiving is often associated with lack of control and unpredictability (Schulz and Martire, 2004).

In contrast to formal caregiving provided by health professionals and being paid by the recipient or any responsible body (e.g., health insurances or the social security system), informal caregiving is provided by nonprofessionals, without financial compensation. To emphasize this lack of remuneration, the term 'informal caregiving' is often used synonymously with 'family caregiving' (Bastawrous, 2013). Services performed by informal caregivers are considered a substantial health care resource, saving the public health care systems hundreds of billions of dollars each year (Arno et al., 1999).

As caregiving may be physically and emotionally strenuous, lasting over a longer period without a predictable development, caregiving is described as a chronic stressor with relevant impact on diverse life domains, such as physical and mental health (Pinquart and Sorensen, 2003, 2007), labor market integration, or the financial situation (Family Caregiver Alliance, 2013). As the label of 'caregiver burden' suggests, caregiving can be seen as strenuous or burdensome. Yet, the term 'caregiver burden' remains vague, as there is no general agreement on its definition, neither at the conceptual level nor at the operational level (Bastawrous, 2013). Generally, caregiver burden describes a variety of different experiences related to caregiving, thus requiring a complex definition. One such definition maintains that caregiver burden is "a multidimensional response to physical, psychological, emotional, social, and financial stressors associated with the caregiving experience" (Kasuya et al., 2000: p. 119). The caregiver burden as a result of potentially distressing caregiving activities relates to 'objective' and 'subjective' aspects of caregiving. The objective burden refers to the objectively observable physical or instrumental care provision in terms of number of hours or type of care provided. In contrast, subjective measures of the caregiver burden mostly relate to emotional or psychological consequences of caregiving; for example, depressive mood or distress (Bastawrous, 2013).

To date, a variety of standardized measurement instruments have been designed to assess the caregivers' feelings of burden, mostly including both objective and subjective indicators of burden (for an overview see Whalen and Buchholz, 2009). However, as a consequence of the multidimensional concept, many instruments include a multitude of constructs, such as impact of caregiving, quality of life, risk, strain, hassles, cost of care, experiences, and domain-specific areas of stress (physical, psychological, emotional, social, or financial). These instruments often assess very detailed aspects of caregiver burden, e.g., worry, isolation, guilt, blame, or fatigue. Conversely, some instruments include positive outcomes of caregiving, such as the satisfaction that results from the caregiving experience (Whalen and Buchholz, 2009).

The Prevalence of Caregiving

As informal or family caregiving is not defined uniformly, prevalence estimates vary according to the underlying definition. However, there is a general consensus that its prevalence is high. Different estimates from the United States are used to illustrate the dimension of caregiving in Western countries. For example, estimates from the National Alliance for Caregiving suggest that 65.7 million persons, and therefore approximately 29% of the US adult population, provide care to an ill, disabled, or aging person (The National Alliance of Caregiving and the American Association of Retired Persons, 2009). Other sources estimate that 52 million persons in the United States provide care to an adult aged over 18 years with disability or illness (Coughlin, 2010). Data from the Alzheimer's Association estimate that around 43.5 million adult caregivers care for someone above age 50, and 14.9 million caregivers care for someone with Alzheimer disease or another type of dementia (Alzheimer's Association, 2011). Additionally, an estimated

5.9 million children in the United States live with severe disabilities, most of them receiving care at home by their parents and families (Perrin, 2002).

The Typical Caregiver

As populations age across most Western countries (European Commission, 2007; U.S. Department of Health and Human Services, 2012), the group of those caring for elderly persons has steadily increased over the past decades. Many old people suffer from one or more chronic conditions where their care cannot be given by professional care providers. In these instances, spouses or children are most likely to care for their elderly family members. Around 70% of 50- to 64-year-old caregivers provide care for an elderly parent. Among caregivers aged over 75, caring for a spouse is the most commonly reported care situation. In the group of spousal caregivers, the proportion of male caregivers is higher than in any other care situation (Wagner and Takagi, 2010).

Based on theoretical concepts of gender role socialization, gender role expectations, and labor market segregation indicating that women more often engage in household activities, it has been suggested that females are more often involved in caregiving than males. However, evidence concerning gender differences in caregiving is inconclusive. In a review from Yee and Schulz (2000), four studies found that women spend more time in caregiving than men, while two studies reported no gender differences, and one study observed that men spend more time in caregiving than women. Despite these inconsistent results, there is some consensus that the proportion of male caregivers has steadily increased over the past years, and that it is especially high in older cohorts (Wagner and Takagi, 2010; Family Caregiver Alliance, 2013).

The average age of caregivers has slightly increased during the past decades and is now around 50 years. The average duration of caregiving is about 4 years with widely varying intensity (Wagner and Takagi, 2010; The National Alliance for Caregiving, 2005, 2009). According to a US study, the average caregiver spends 21 h with care provision per week, where about half of the respondents indicated a caregiving provision of less than 8 h, but where almost 20% reported to spend more than 40 h weekly (The National Alliance for Caregiving, 2005). Despite the wide range of care intensity, it is generally assumed that the number of hours caring for someone increases with the age of the caregiver (Wagner and Takagi, 2010; The National Alliance for Caregiving, 2005, 2009).

Around three of four caregivers are employed. Still, over 50% of middle-aged employed caregivers indicate that their caregiving task affects their work life such that they report leaving work early or come in late as a consequence of their caregiving role (Wagner and Takagi, 2010). According to a review from 2007, caregivers engaged with low amounts of time in caregiving had the same chance of labor market participation as noncaregivers. In contrast, caregivers who were heavily involved in caregiving were less likely to work than noncaregivers. Likewise, researchers found an inverse relationship between time spent on caregiving and time spent on participation in the labor market (Lilly et al., 2007).

Caregiving and Its Multifaceted Consequences

Although caregiving is a highly important resource for society and individuals in need of care, there is a consensus on the fact that caregiving is a chronic stressor affecting different life domains of caregivers. Caregiving has therefore been analyzed within a stress-theoretical framework that considers caregiving as the proliferation or spread of stress from primary stressors to increased risk of physical or psychological morbidity of the caregiver (Schulz and Martire, 2004; Pearlin et al., 1997).

Within this analytical framework, objective primary stressors are composed of characteristics of the care receivers' health (e.g., level of functioning, severity of disability, cognitive impairment) and the type and intensity of caring activities. Further objective stressors are care receivers' behavioral problems including verbal and physical aggression, agitation, psychotic symptoms (e.g., hallucinations and delusions), sleep disturbances, depression, and obstructive behavior (Ornstein and Gaugler, 2012). Interestingly, higher levels of care recipient behavior problems were more consistently related to the caregiver burden in terms of poor health than were care receivers' impairment and intensity of caregiving (Pinquart and Sorensen, 2007), possibly due to their unpredictability.

As caring for a person with cognitive impairment seems particularly stressful, dementia caregiving provides an instructive example of the relation between objective stressors and its consequences for caregivers. Dementia caregiving is therefore the predominant health condition studied in the caregiving literature (Schulz and Martire, 2004). For example, dementia caregivers spend significantly more time providing care and supervision than nondementia caregivers and are more often confronted with behavioral problems of care recipients (Ornstein and Gaugler, 2012). As a consequence of these primary stressors, persons caring for someone with cognitive problems report higher caregiver burden and suffer from more mental and physical health problems than nondementia caregivers (Schulz and Martire, 2004; Pinquart and Sorensen, 2003, 2007).

Besides primary stressors related to care receiver characteristics, stress-coping models also include the examination of secondary stressors, mainly related to the role conflicts due to caregiving demands (Schulz and Martire, 2004; Pearlin et al., 1997). For example, long-term care for a family member may increase the risk of family conflicts in case of disagreement on caregiving roles, division of responsibilities, or the way of carrying out caregiving tasks. Additionally, work-related problems such as being tired or absent from work, missing job opportunities, or missing chances for job promotion are potential problems that occur as a consequence of primary stressors of caregiving. Further consequences of caregiving including financial difficulties or social isolation were described (Ranmuthugala et al., 2009). Again, dementia caregivers seem to be particularly vulnerable to secondary stressors as they more often face complications with their involvement in the labor market, and as they report more limitations in their leisure time and their engagement in social relationships (Etters et al., 2008).

Based on the stress-health model, primary (care receivers' characteristics, type of care provided) and secondary stressors (e.g., role conflicts, financial hardship) result in the experience

of stress, in case caregivers evaluate the demands as threatening and their coping resources as inadequate. Research has documented the physiological responses related to caregiving in terms of stress hormones, immune competence, and medication use (Vitaliano et al., 2003). It is assumed that chronically stressful experience elicits negative emotional, physiological, and behavioral responses that increase the risk of physical and psychiatric morbidity (Schulz and Martire, 2004). According to a comprehensive meta-analysis, caregivers report worse physical and psychological health than noncaregivers. More specifically, they suffer from more stress, more depressive symptoms, lower levels of subjective well-being, poorer physical health, and lower self-efficacy than noncaregivers. Again, the health differences were highest in dementia caregivers (Pinquart and Sorensen, 2003). Ultimately, caregivers reporting a burden related to their caregiving activity had a 63% increased mortality risk compared to that of persons who were not involved in caregiving. Conversely, caregivers who did not report caregiver burden were not likely to show an increased mortality risk compared to noncaregivers (Schulz and Beach, 1999).

Since most of the research has concentrated on negative effects of caregiving, criticism concerning the focus on detrimental caregiving consequences has been raised, and it has been claimed that positive aspects of caregiving need to be included in research as well. In fact, several studies observed that persons providing care feel enriched by their caregiving role due to the fact that caregiving contributes to personal growth, a stronger purpose in life, a feeling of mastery, or a sense of usefulness (Kramer, 1997). Yet, it remains unclear how the positive and negative experiences related to caregiving interact.

Whether caregiving is perceived as stressful experience or not may also depend on a variety of factors moderating and/or mediating the effects on caregiver outcomes. Socioeconomic position, psychosocial resources, sociodemographic characteristics, or psychological traits play an important role in predicting the caregiver burden. For example, caregivers in higher socioeconomic position are at lower risk of poor health than caregivers in disadvantaged social positions (Pinquart and Sorensen, 2007). It is supposed that caregivers in privileged social positions have better access to the health care system and are less often exposed to additional stressors unrelated to caregiving. Social support is a further resource potentially important to reduce the caregiver burden as social support may buffer the stressors related to the caregiver role, strengthen coping strategies, and enhance health-promoting behaviors. Evidence from an extensive meta-analysis supports this notion by showing that informal support of caregivers is associated with better physical health (Pinquart and Sorensen, 2007). Also, psychological resources such as self-efficacy or self-esteem of caregivers have been identified as protective factors in the experience of caregiver burden. Furthermore, age and gender may have impact on the development of caregiver strain and ill-health of caregivers. Not surprisingly, higher age was related to poorer physical health of caregivers (Pinquart and Sorensen, 2007), and it has been suggested that the health effects of caregiving are more serious in female than in male caregivers. Caregiving women reported somehow higher burden, lower subjective well-being, more depressive symptoms, and lower physical health than caregiving men (Pinquart and Sorensen, 2006). Finally, the quality of the relationship between the caregiver and the care receiver might be an important factor in the perception of burden and subsequent health outcomes. A recent review indicated that caregiver–care receiver mutuality is an important correlate of mental health and emotional well-being of the caregiver (Park and Schumacher, 2013).

Future Challenges

Demographic changes and further progress in medical treatment of chronic disorders may lead to an increased importance of informal caregiving in the near future. For example, recent estimates claim that by the year 2040, around 21% of North Americans will be aged over 65 years (U.S. Department of Health and Human Services, 2012), and estimates for Europe predict that the old age dependency ratio, expressed by the number of people aged over 65 per number of people aged 15–64, will increase from 25% in 2007 to 53% in 2050 (European Commission, 2007). As it is highly unlikely that the aging population will be adequately supplied by professional care, these developments result in a high need of informal care. In addition, progress in medical treatment will extend caregiving episodes, e.g., through drug therapies, improving a patient's functional status and extending his or her home care.

Although the overall need for informal caregiving is likely to increase, changes in family structures and social roles may compromise the potential of informal caregiving or may at least increase the caregiver burden. Family structures are likely to change such that future cohorts of elderly will have smaller families and, in consequence, fewer children available for engagement in caregiving. Additionally, as female labor market participation will increase in the near future, female resources to provide care will be reduced.

These societal changes in family composition and in the distribution of social norms within families will result in a growing concern about opportunities and threats of caregiving in the future. Obviously, caregiving is closely related to demographic changes and level of functioning among aging generations. These developments call for action at two levels. First, at the individual level, interventions targeted to reduce the burden on caregivers need to be established. Experiences with support groups have shown promising results in enhancing caregivers' subjective well-being (Chien et al., 2011). Second, at the macro-social level, the challenge of caregiver burden has to be addressed by appropriate initiatives from social and health policy as well as from supportive private sector programs.

Cargo Cults

Lamont Lindstrom, University of Tulsa, Tulsa, OK, USA

Abstract

Cargo cult spread in the 1950s as a new cover term for Melanesian social movements, although it has also labeled ritual political–economic endeavors elsewhere. In these movements, islanders turned to religious ritual to obtain 'cargo' (or *kago* in Melanesian Pidgin English). The term is rich in meaning. It has signified manufactured goods or money, a new political order, local sovereignty and the withdrawal of colonial rulers, or even human salvation. Cargo cult prophets devised or revived ritual practices, creating new communities waiting for cargo's arrival. Although anthropologists have largely abandoned the term, cargo cult survives in popular media, journalistic, and literary circles to castigate or celebrate all sorts of untoward and wild desire.

The Birth of Cargo Cult

Melanesian cargo cults, so they came to be called, boomed in the 1950s. These southwest Pacific social movements attracted the attention of colonial administrators, ethnographers, journalists, and filmmakers. Although anthropologists borrowed and then refined the term in comparative research and analysis, the label quickly spread beyond ethnographic purviews into sometimes unexpected corners of popular culture. In the final scenes, for example, of the 1962 film *Mondo Cane*, Gualtiero Jacopetti's original 'shockumentary,' we watch yearning Papua New Guinea islanders clustered around a huge, roughly made wooden model airplane. They are gathered high up in the mountains, sitting on a new homemade airstrip carved out of the forest. Their eyes eagerly search the skies, so the narrator tells us, for airplanes full of wonderful cargo that they expect will soon arrive. But they will be disappointed. No cargo planes will land. These islanders are the misguided followers of a cargo cult.

Anthropologists and others, during the first half of the twentieth century, noted and described a variety of island movements and miscellaneous social disturbance throughout Melanesia (that part of Oceania which today comprises the Indonesian province of West Papua, and the southwest Pacific island nations Papua New Guinea, Solomon Islands, Vanuatu, Fiji, and New Caledonia). Australian colonial anthropologist F.E. Williams' (1923) account of the 'Vailala Madness' in Papua was one of the more comprehensive descriptions of a movement that erupted in the earlier years of European domination of these islands. It was not until after the Pacific War, however, that Melanesian social movements would come to be bundled together under the new rubric of cargo cult. Peter Worsley, who compiled an important initial overview and survey, characterized cargo cults as:

> strange religious movements in the South Pacific during the last few decades. In these movements, a prophet announces the imminence of the end of the world in a cataclysm which will destroy everything. Then the ancestors will return, or God, or some other liberating power, will appear, bringing all the goods the people desire, and ushering in a reign of eternal bliss (1957: 11).

Following the Second World War, anthropological concern was gradually shifting from describing static social orders through the lens of structural functionalism, which presumed cultural continuity, to issues of development and upheaval. In the 1950s, social change and revolution became difficult to ignore. Two celebrated accounts of the history of protest and rebellion appeared in the same decade as the first cargo cult monographs: Norman Cohn's *Pursuit of the Millennium* (1957) and Eric Hobsbawm's *Primitive Rebels* (1959). Issues of protest, insurrection, insurgence, and upheaval were then in the air and these questions percolated even in the far Melanesian fringes of the colonial world. The war had mortally undermined the colonial system, although the final effects of this would not play out in the Pacific until the 1970s. After 1945, new problems of social change, syncretism, governance, and new challenges to colonial authority attracted increased anthropological attention, and the cargo cult emerged as a central problem which confronted both colonial power and academic social theory.

The cargo cult story depicted South Pacific islanders as desperate, confused, or sometimes misled who turned to religious ritual (which was sometimes traditional and sometimes innovative) in order to obtain cargo. They expected and worked for a sudden, miraculous transformation in their lives and villages. Steinbaurer, in 1979, published a catalog of 186 cargo cults and others have counted up to 400–500 of these, although this has required some stretching and diversifying the label, both temporally and spatially. Especially notable or long-lived cargo cults (or Melanesian social movements that attracted the label) include the John Frum and Nagriamel movements of Vanuatu, the Christian Fellowship Church and the Moro Movement of the Solomon Islands, and the Paliau and Yali movements, Hahalis Welfare Society, Pomio Kivung, and Peli Association of Papua New Guinea.

Leading these movements, cult prophets commonly drew on Christian millenarianism, sometimes conflating the arrival of cargo with Christ's second coming and Judgment Day (locally often called 'Last Day'). The word 'cargo' (or *kago* in Melanesian Pidgin English) is rich in meaning. It has signified various sorts of manufactured goods (vehicles, packaged foods, refrigerators, guns, tools, and the like) and European money. Or cargo could represent the struggle for a new political order,

the assertion of local sovereignty, and the withdrawal of colonial rulers (see Burridge, 1960). Or, again, cargo more metaphorically could signify human salvation and a final, successful transcendence of everyday reality (Strelen, 1977).

The first academic accounts of cargo cults featured in anthropological journals beginning in the early 1950s. The first ethnographic monographs appeared in 1956. The period between 1956 and 1964 was cargo cult's golden age (or literary high point, at least). During these years, six important anthropological analyses were published. Five of these dealt with particular cargo movements: Jean Guiart (1956) on Tanna Island's John Frum Movement in what was then the colonial New Hebrides; Margaret Mead (1956) and Theodore Schwartz (1962) on the Paliau Movement of Manus, Admiralty Islands; Kenelm Burridge (1960) on northern Madang movements in Papua New Guinea; and, not too far away, Peter Lawrence's account of the Yali Movement (1964). The sixth, now classic volume was Peter Worsley's comparative compendium of Pacific cargo cults, *The Trumpet Shall Sound* (1957). One might also include here Robert Maher's *New Men of Papua: A Study in Culture Change* (1961) that described the Tommy Kabu Movement of the Purari River delta area of Papua, although Maher did not use cargo cult idiom to frame his analysis. The term only appeared as an afterthought on the book's final page where Maher warned that Purari people, although up to then pragmatic, could turn instead to cargo cult should their growing desire for social change be thwarted. After the mid-1960s, cargo literature and accounts hugely expanded as ethnographers described more and more Pacific social movements under the cargo cult rubric. Cargo cults, too, demanded increased attention as one of the main theoretical puzzles of Pacific ethnography (why, when, where, and how does cargoism erupt). Cargo cult analyses also informed grander anthropological theories of cultural organization and social change (see Jarvie, 1964; Jebens, 2004).

The Cargo Cult Label

The term cargo cult first appeared in the November 1945 issue of the colonial news magazine *Pacific Islands Monthly*. That month, Norris Mervyn Bird, whom the editors identified as an old territories' resident, wrote to warn of postwar flare-ups among islanders misled by ill-digested Christian teaching and an increasingly liberal and dangerous colonial policy. Bird was particularly perturbed that the new Labor Party government in Canberra might liberalize its colonial native affairs policies, including maintaining islander militias into the postwar era. Several anthropologists including Lucy Mair and H. Ian Hogbin, who then lectured at the Australian Army School of Civil Affairs in Canberra, adopted the term soon afterward. This quickly spread through Australian academia and then into anthropological circles overseas as anthropologists and others borrowed 'cargo cult' to label almost any sort of organized village-based social movement with religious and political aspirations – movements which were increasingly on colonialist and academic radar throughout Melanesia.

Although cargo cult, the label, dates only back to 1945, it spread rapidly as a popular and soon ubiquitous cover term for Pacific social movements. Some extended it back in time to label recorded political disturbances as old as 1857 (Steinbauer, 1979). The term also spilled beyond Melanesia and was also applied to movements in the Polynesian and Micronesian cultural regions of the Pacific. Although an improvement over 'Vailala Madness' and other prewar terms for island social movements, the label cargo cult proved problematic in several ways. Islanders involved in such movements always aspired to achieve many things beyond simple cargo, or material goods themselves. And movement organization was often misunderstood in cultic terms. More than one observer has had to protest that some social movement in question was 'neither cargo nor cult' (e.g., Kaplan, 1995). Moreover, critics within the Pacific and beyond also quickly adopted the term as a form of political abuse. Some politicians today continue to belittle the plans and aspirations of their rivals by deprecating these as 'cargo cultist.' Despite cargo cult's popularity, from the beginning anthropologists juggled a long list of alternative labels. These have included nativistic movements, vitalization or revitalization movements, accommodation, acculturation, adaptation, adjustment, dynamistic, or enthusiastic movements, messianic movements, millenarian movements, enthusiastic movements, crisis cults, Holy Spirit movements, protonationalist movements, culture-contact movements, and more. These alternative labels appreciated cargo cult's affinities with social movements elsewhere also sparked by the global spread of the colonialist and capitalist systems. Melanesian cargo cults were in significant ways similar to the North American Ghost Dance and Native American Church, China's Boxer Rebellion, and Mau Mau of East Africa, all local reactions to globalizing political and economic forces.

Cargo Belief

The defining aspect of cargo ideology was, of course, unrequited desire for cargo itself. Cultists sought the arrival of ships full of cargo: manufactured goods and tinned foods, vehicles, weapons, and money. After observing military transport during the Pacific War, cultists also began scanning their horizons for cargo submarines and planes. The particulars of desired cargo, as reported, reflected not only local aspirations but also stereotypic presumptions of what islanders should want. Following the war, refrigerators for example, occupied a suspiciously prominent place in many such reported cargo lists and one might expect the refrigerator to be principally an object of western, not island, desire (Lindstrom, 1996).

Details of cargo belief varied from movement to movement. A prevalent theme was the assertion that island ancestors were somehow involved in the production of manufactured goods. During some cults, islanders spun stories of a technologically wise ancestor who long ago had sailed away to America, Europe, or Australia and there taught the secrets of cargo, sometimes leaving behind his less accomplished brother, who was ancestral to less technologically advanced island communities. In others, cargo myth presumed that wily Europeans had stolen industrial knowledge from Pacific ancestors, or were stealing the cargo itself that ancestors were beneficiently shipping back home to the islands. In either case, people invented new rituals to induce the dead to reroute cargo flows and, sometimes, to reanimate and return home aboard cargo-filled ships and planes and reunite with their descendants.

The cultic task was to penetrate the secret knowledge people presumed to support European technological and political prowess and to acquire this knowledge and goods alike. The human task was to restore local dignity and realize egalitarian relations with troublesome white newcomers (Lattas, 1998).

After the Pacific War, the American military occasionally assumed the role of cargo provider. Many Melanesians, particularly those recruited to work at allied bases on Efate and Espiritu Santo in the New Hebrides, Vanuatu, Guadalcanal in the Solomon Islands, and Manus, Hollandia, and elsewhere in New Guinea, received better pay and gained access to a welcome variety of new wartime goods and services. After the militaries withdrew from most of the southwest Pacific, money and goods became scarcer. John Frum movement supporters active on Tanna began predicting the return of US military units along with the wartime cargo they had enjoyed as labor corps recruits. John Frum leaders also incorporated experience of military routines and symbols into their postwar cult ritual and liturgy, including drill team marching, bamboo rifles, red crosses (from Army ambulances), numbered dog (identification) tags, khaki uniforms, and American flags (Figure 1).

Many movements, in addition to simple material goods, pursued various sorts of world transformation. This, too, partly reflected political conditions at the end of the Pacific War. The Japanese advance had dislodged the Dutch and the Australians from much of New Guinea as well as the British from the Solomon Islands. Large American occupation forces similarly destabilized colonial authority in the New Hebrides and, to a degree, in New Caledonia and Fiji. At war's end, when colonial powers moved to reestablish their authority, many islanders who had largely governed themselves during the war years resisted this reassertion of European control. Some postwar cult prophets in response began predicting that ancestors, or returning Americans, would drive the colonial powers from the region. In these areas, cargo cults were as Jean Guiart (1951) argued 'forerunners of Melanesian nationalism.'

Figure 1 John Frum followers raise American flag at Sulphur Bay movement headquarters (copyright Lamont Lindstrom).

In addition to articulating desire for freedom, dignity, and independence from European domination, cult prophets often predicted more millenarian sorts of change. Mountains would flatten and valleys would rise up. Land would become sea, and the seas dry up. Cultists expected the coming of a new world and transformed personhood, and many cult rituals offered motifs and elements of rebirth, or baptism, to mark the advent of a new order. Two common cargo prophesies were that the dead would come back to life, and that the skins of the faithful would whiten. The first of these prophecies reflected the importance of ancestral spirits in traditional island religions and their connections with fertility and production. The second responded to the stark racial inequalities of colonialist regimes where Europeans controlled access to money, goods, and education. Some read these desires in Christian, or at least syncretic, terms as signifying a universal human quest for salvation and ultimate transcendence of everyday existence and sourced cult ideologies to the more millennially inclined Christian messages offered by missions, such as the Seventh-day Adventists, that spread throughout the region before the war. Whether or not particular cultists embraced this strand of millennialist Christian theology, much cult ideology did expect world transformations of various sorts. Burridge (1960, 1969) summarized all cargo ideology as a new 'myth-dream': the fusion of shared hopes, desires, and imagined possibilities that a prophet or visionary brought into communal focus.

Cult Organization

Orality rather than literacy continues to characterize much of Melanesia. People communicate by talking. All sorts of rumor, news, and speculation flow from village to village – some of this still about mysterious sightings, dreams of the future, or prophetic visions. Only some of these stories attract much public attention, however, let alone a following. Anthropologists attempted to figure why cargo movements occurred in one village while bypassing another. Two important factors proposed to explain the distribution of cult outbreaks were the degree of people's sense of 'relative deprivation' – how unhappy they were with their current lives vis-à-vis the past, their future aspirations, or their neighbors – and the absence of a strong, local power structure. Where people did not feel relatively deprived, they were less likely to follow cargo prophets. And where village leaders remained powerful (whether these leaders were chiefs or what, in Melanesian Pidgin English, are called 'big-men'), they usually could deflect upstart cargo cult enthusiasm, chase away prophets, and stifle the local spread of a movement.

Cargo movements typically were sparked by local prophets who foretold the return of ancestors or of ancestral favor and prescribed what people must do in order to obtain cargo, instigating, for example, novel sorts of dance, exchange, and other ritual. Cult leaders claimed special knowledge of supernatural instruction and usually also privileged strategies to acquire such. Given island orality, prophecy spread largely by word of mouth. Prophets or their representatives sometimes itinerated throughout a region to spread the message or, emulating Christianity, they established regular holy days and headquarters where followers periodically convened. John Frum leaders, for example, established a new ritual calendar which included weekly Friday night meetings at the Sulphur Bay movement headquarters on the east Tanna coast, and an annual celebration every February 15th that celebrated cult founders. During these events, they enjoyed the opportunity to plan, circulate information, and reinforce their message among the followers.

Sometimes cargo prophets urged the revival of traditional ceremony and practice that European missionaries and officials had devalued, including dance, kava drinking, male initiation ritual, polygyny, and so forth. Others focused on ritually miming European practices and styles, including dinner tables, dress, and letter writing. Cargo prophets often instructed people to drill and march. The faithful cleared new airfields, as in Jacopetti's *Mondo Cane*, and built makeshift cargo warehouses to store wealth expected soon to arrive. Prophets also often advised followers that the ancestors required novel offerings of food, flowers, or money to be left in graveyards in order for cargo to materialize. They sometimes instructed followers to dig up crops, kill their pigs, or as did John Frum leaders on Tanna, discard all European money in order to open the gate to the cargo road. Some cults engineered the abolition of marriage exchange and incest prohibition, and prophets and followers alike engaged in unrestrained sexuality (Rimoldi and Rimoldi, 1992). Elsewhere, prophets outlawed sex entirely as ritually necessary to ensure cargo's arrival. In regions where movements became politically dominant, as occasionally happened in Tanna's John Frum areas, leaders instituted police forces and cult courts to enforce their edicts and protect movement orthodoxy.

In much of Melanesia, knowledge remains a politically valued resource and inspiration, not personal creativity, the dominant mechanism of socially legitimate knowledge production. Men achieve personal reputation and also political status with a comprehensive grasp of family genealogy, history, personal and place names, ritual procedures, and curing and divination skills. Inspired knowledge of cargo has had similar political weight. Prophetic messages of all sorts, in fact, are not unusual in Melanesia. Many people, even though today longtime Christians, continue to sense the presence of ancestral ghosts and other spirits. It is not uncommon for men and women to acquire knowledge and information in their dreams. Dreamers whose cargo messages were accepted as useful and true by a community became leaders of the movements that formed around them, although sometimes others stepped in to organize and distribute the prophetic messages that dreamers provided. Women, for instance, have also been cargo prophets, although men typically appropriated and broadcast the messages that less mobile, less discursive women received in their dreams or otherwise.

Cargo prophesies have united people – at least temporarily – into areal organizations that conjoined villages and kin groups from across a region (Worsley, 1957). Participation in many of these movements was much larger than in village and kin-based Melanesian social groupings typically of modest size. Broader social unity, in fact, was an explicit message and goal in many movements, and cult ideology focused demand for social cooperation and harmony. Prophets and leaders worked to get everyone involved in cult ritual; for example, mass dances and marches to invite ancestral arrival, or ritual procedures to wash and bless money to promote its reproduction. Novel movement rituals of communal dancing, drilling, and marching, in fact, represented and enacted new cultic social unity. Prophets also often preached against socially divisive practices of sorcery, in particular, along with other threats to group unity. Attempts to reengineer marital and sexual practice within movements typically aimed to reduce intergroup conflict and to encourage a unified community. Collapse of movement solidarity served sometimes to excuse the failure of prophecy. Cargo did not arrive because followers did not fully obey prophetic command to create a stable, harmonious community.

The history of most cargo cults was short. Followers abandoned a prophet and his movement when no cargo arrived and the world did not transform. Active culting melted back down into background, ordinary cargo desire (see Jebens, 2010). Some cargo cults, however, have been successfully institutionalized and continue to be active in different form. John Frum on Tanna, for example, which began in the late 1930s, 70 years later is managed by third and fourth generation leaders, and has elected members to Vanuatu's national parliament (Tabani, 2008). Other cargo cults have similarly been institutionalized as political parties, new religions, or both. The Peli Association, Pomio Kivung, and New Britain's Tutukuval Isukal in Papua New Guinea are successful political organizations at the local level (Lattas, 1998; Whitehouse, 1995; Billings, 2002). The Christian Fellowship Church thrives today on New Georgia, Solomon Islands as a syncretic church and notably successful business enterprise engaged in forestry, logging, and fisheries.

Cargo Cults and Melanesian Culture

Anthropologists of Melanesia used to argue that the region suffered an enduring, bedrock cargo thinking, or cargo mentality, or cargoism, or even cargo culture. This made it difficult to discern exactly when a particular cargo cult began or ended. Everyday cultic frisson kept the atmosphere charged even when no cargo prophets were actively stirring things up. One can certainly contextualize cargo belief and cult structure within enduring, fundamental patterns in Melanesian cultures. Everywhere, the exchange of goods and wealth objects is an important aspect of creating and maintaining social relationships. People give one another garden produce, pigs, mats and baskets, traditional shell and contemporary money, and other valuables to celebrate births and marriages, and to mourn deaths. Moreover, men and women earn social reputation and political influence through generous giving. Cultic focus on wealth, thus, elaborated ubiquitous concern with the political

management of economic production and exchange. And, because people believe that ancestral supervision ensures the fertility of people, gardens, and pigs, it made sense to turn to ancestors and spirits also to acquire new kinds of goods such as money or shotguns or tinned peaches. Cargo cult ceremony paralleled traditional ritual practice that ensured ancestral benevolence.

Many islanders also continue to believe that ancestors speak to them in dreams, providing important knowledge, hints of the future, and instruction for proper living. Messages about the arrival of cargo ships and planes were similar to other sorts of spiritual communication. Furthermore, some have suggested that Melanesian conceptions of time and social transformation are 'episodic' rather than developmental (McDowell, 1988). People presume that sudden transformations are normal; that one cosmic order at any moment may replace another. Prophecies of cargo's arrival, the return of the dead, and the emergence of a new world are more compelling where people do not believe that the future must develop incrementally over time from the present. Finally, cultic organization – a community of believers who follow cult prophets and leaders – resembled ordinary social organization in much of Melanesia where big-men attract followers by managing the exchange of goods and information (Cochrane, 1970). Cargo prophets, along these lines, functioned as just another sort of traditional island leader.

If cargo cults are a Pacific version of millenarian movements that erupt everywhere in times of uncertainty and change, then these underlying aspects of Melanesian culture help explain the regional particulars of cult organization and the details of cargo ideology (Trompf, 1990). More than this, some have suggested that cargo culting is an indigenous Melanesian form of political organization and change that predates colonial interference in the region. If this is the case, nativistic, revivalistic, and utopian social movements in Melanesia may not quiet down and ultimately disappear, as many have predicted, despite the end of colonialism and gradual economic development throughout the region.

Cargo Cult Futures

Cargo cults may continue to erupt, or they may prove to have been a twentieth century reaction to globalization, colonial inequalities, and the disruptions of world war. The most successful movements, however, have survived into the twenty-first century, now institutionalized as political parties, churches, and business enterprises in Vanuatu, Solomon Islands, and Papua New Guinea. Some, like John Frum on Tanna, also serve as minor tourist attractions celebrated and promoted by touristic entrepreneurs. Much of the desire and energy that once animated these social movements flow today into new Evangelical and Pentecostal Christian mission enterprises. Beginning in the 1980s, fundamentalist Christian missions based in Australia, New Zealand, and the United States notably strengthened their presence in the Pacific. Influenced by this renewed Christian millenarianism, many islanders have become involved in Holy Spirit movements. Rather than waiting for cargo ships, followers seek instead to be possessed by the Holy Ghost to bring about sudden transformations of self, society, and world. Typically, local Christian leaders often also undertake healing and antisorcery campaigns, cleansing villages of hidden sorcery paraphernalia believed to be causing illness, death, and disorder. New Christian prophets predict the Last Day – the return not so much of cargo but of Christ – and the impending establishment of a new cosmos. What could be called neo-cargoism has also sometimes been sparked by failed or successful development projects such as Lihir Island's gold mine (Bainton, 2010). As Pacific islanders are increasingly absorbed into a global, capitalist order where economic inequalities persist, and even deepen, social movements (Christian, cargoist, and otherwise) certainly will persist.

Whatever happens to cargo cults themselves in the Pacific, the label cargo cult is now widely applied – and no longer just in Melanesia (Lindstrom, 1993). Cargo culting today is anything that some critic depreciates. Any fervid desire for wealth or goods that people pursue with apparently irrational means can be condemned as cargo cultic, and the Internet abounds with examples of creative uses of the cargo cult label far almost everywhere. Almost anything might be called cargo cult if it: demonstrates fervid desire (for wealth, or whatever); involves some group or collectivity of the desirous; and if these desires, or purported means to achieve them, can be discredited as irrational. Or, "the distilled essence of cargo cult, in this most simplified delineation of the term, is a tragic relationship between rational ends and irrational means – between genuine desire and ineffective practice" (Lindstrom, 1993: 185–186). Cargo desire, though, can also sometimes be an honorable sentiment as it was, occasionally, in stories of Melanesian cultists. Good cargo culting focuses on personal development, creativity, and individual freedom while bad and tragic cargo desire merely seeks tawdry material goods or dubious political programs, quick but ineffective fixes to life's problems.

Cargo cult is a just-so story about a peculiarly modern mode of desiring that is always ultimately unrequited, unquenchable, and never ending. These underlying cultural currents of, and about, desire sustain cargo cult's continuing popularity and use, despite the particularities of its deployment online and elsewhere. As cultural moderns we take desire itself, no matter its good or bad objects, to be naturally unending. We rightly desire human perfectibility, freedom, and wealth but we would be astonished should we one day actually achieve this. Self-development is, and should be, an infinite task. Cargo cultists, both good and bad, presume desire naturally to be an unquenchable, unrequited human condition. Tales of the cargo cult have served to phrase our understandings of human desire in constant, universal form. We continue to appreciate a universal cargo cult story, now relocated from Melanesian islanders to desiring humans everywhere.

Carnival

Abstract

Within the European Christian tradition, Carnival is the festive period that either came some days before Lent or signaled the start of Lent itself. It is a time when people abstained from eating meat, but was primarily marked by large public celebrations that included costumes, masks, music, dances and street theater. With the spread of European colonialism, Carnival became a global phenomenon. Carnivals that have developed in other regions around the world have reflected the local, indigenous or immigrant cultures that were present in those societies.

Carnival is not simply a single event celebrated in many places. Everywhere that Carnivals have taken root and grown they have become unique events unto themselves. Whatever soil they germinate from tends to influence their final flowering. In the United States the term Carnival is often applied to a variety of fairs or temporary amusement parks that have little or nothing to do with Carnival or Mardi Gras as it is known in New Orleans, Louisiana, and Mobile, Alabama. The latter are examples of New World versions of an old world festival whose origins can be traced in Europe to about the AD tenth century.

From the end of the 900s to the middle of the 1100s some reference is made in Latin documents to *carnelevare*, a word interpreted to mean literally 'to lift up the flesh, or remove the meat.' The term is used in these documents generally to refer to a regular time at which people were meant to settle debts. However, the origin of the name 'Carnival' is disputed between those who argue for a connection to the Italian word 'carne' (meat), and those that argue a link with the word 'carrus' (car). The argument here really concerns the putative origins of the modern festival. The 'carne' camp would suggest an origin within Christianity, linking the festive traditions to the Lenten season, while the 'carro' camp would allow the origins of the festival to be much earlier with pre-Christian cultural traditions. By far the most common Folk etymologies that exist agree with the connection to the later Latin expression 'carne vale,' which means 'farewell to meat.' The word carne may also be translated as flesh, and thus some interpret the expression carne vale as farewell to one's corporeal self and therefore as an invitation to free oneself of one's previous identity. The alternate origin story stems from the Roman name for the festival of the Navigium Isidis (ship of Isis). Indeed there were such processions marked by costuming, music and the carrying of what we might consider 'floats' today. However these forms of celebration, marked by these general characteristics, may be found in many contexts geographically and historically.

A document dating back to the year AD 1140 alludes to the slaughter of animals and a parade through Rome in anticipation of Lent. Lent in the Christian calendar lasts 40 days and culminates in Easter Sunday. It represents the 40 days that Jesus retreated into the wilderness to meditate, and to undertake fast. Lent is preceded by Ash Wednesday, at which time ashes taken from the burned palm fronds of the previous year's Palm Sunday are applied to the forehead of the believer in the shape of a cross. Carnival was incorporated into the Christian calendar as a final festive moment at which meat could be consumed and frivolity exercised in anticipation of the seriousness of the Lenten season.

In the fifteenth and sixteenth centuries writers began to associate the rites of Carnival with ancient Roman and Greek antecedents such as the Saturnalia, Bacchanalia, and Lupercalia. There does not appear to be any direct connection with these festivals, however, and there is a large gap, historically speaking, between the last mention of these ancient rites and the first references to medieval Carnival. What appears to be the most likely scenario for the origins of medieval Carnival is that it served as a sort of ritual magnet to surviving pagan activities. That is, the ritual of a celebration before Lent attracted to it many non-Christian practices and rituals that had been enacted at approximately the same time as Carnival. These included a host of fertility rites; agricultural and hunting rituals; and forms of sun, river, or mountain worship. Many of these rituals were undoubtedly quite ancient themselves, but had clearly gone through enormous changes through the ages before they became incorporated as features of Carnival. The costuming traditions of many of today's European Carnivals bear traces of these ancient rites just as many new world carnivals bear traces of ancient African, South Asian, and Native American/Amerindian practices.

Within the medieval European context, some of the most elaborate and well-known traditions, including Carnival parades, masquerade balls and costumed characters, were first recorded in medieval Italy with Venice emerging as the acme of the Carnival arts. From Italy, Carnival traditions spread to the Catholic nations of Spain, Portugal, and France. From France, they spread to the Rhineland of Germany, to Greece and to the French colonies of North America and the Caribbean. From Spain and Portugal, Carnival accompanied the Catholic colonization to the Caribbean and Latin America. The next section will deal with the proliferation of Carnivals in Europe followed by a discussion of Carnival's spread through colonization, conquest and empire and the addition of cultural elements from Africa, South Asia, and Native America. Carnival from the fourteenth to the sixteenth century developed into one of the most important celebrations in Europe; so much so that by the seventeenth and eighteenth centuries the Church attempted to radically reform what was perceived to be an unmitigated adventure in sin and the pursuit of pleasure. But by the early

nineteenth century, especially in the urban centers of Western Europe, Carnival had made a comeback, especially in Paris.

Northern Europe

The two major Carnivals of France are the Nice Carnival and the Paris Carnival. The Nice Carnival was held as far back as 1294, and is still held annually, attracting over a million visitors yearly during the two weeks preceding Lent. The Paris Carnival occurs after the Feast of Fools and dates back to the sixteenth century or earlier. To the north, in Belgium there are several notable Carnivals. The Carnival of Binche in Belgium has a history dating back at least to the fourteenth century. Although, like most Carnivals, the season itself begins many weeks prior, major parades are held over the three days before Lent; the most important participants are the Gilles, who go out in traditional costumes on Shrove Tuesday and throw blood oranges to the crowd. In 2003, the Carnival of Binche was listed as one of the Masterpieces of the Oral and Intangible Heritage of Humanity by UNESCO. The Carnival at Aalst, in Belgium, which is celebrated for the full week preceding Ash Wednesday, itself was inscribed in 2010.

While the most celebrated and by far the largest Carnival in England is Notting Hill Carnival (see below) historically the season immediately before Lent was called Shrovetide and was a time for confessing sins (also known as 'shriving'). This period was generally met with fewer festivities than the mainland European Carnivals and many of these did not survive the sixteenth-century English Reformation, although England has a host of other seasonal festivals. In German-speaking countries, two distinct varieties of Carnivals are observed. The Rheinish Carnival is held in the west of Germany. The Cologne Carnival is the largest and most famous of these. Unique to this celebration is 'Weiberfastnacht,' held in commemoration of an 1824 revolt by washer-women. On this day women traditionally cut off men's neck ties and are permitted to kiss any man they like. The Carnival of southwestern Germany is known as Fastnacht. This festival takes place in Baden and Swabia, Switzerland, Alsace and Vorarlberg in Western Austria. It is linked to pre-Christian rites dedicated to the expulsion of winter and the renewal of spring and growth. Carnival in the Netherlands is also called 'Vastenavond' or 'Vastelaovend(j),' and is mostly celebrated in Catholic regions of the country, mainly in the south. Dutch Carnival is officially celebrated on the Sunday through Tuesday preceding Ash Wednesday. Although there are many traditions that are region-specific, some common characteristics of Dutch Carnival include a parade, a 'prince' plus cortège ('Council of 11'), a farmer's wedding (boerenbruiloft), and eating herring on Ash Wednesday. Dutch Carnival is perhaps best remembered in the modern era through the celebrated paintings of fifteenth-century painter Hieronymus Bosch.

Southern Europe

The most famous Carnival in Italy is the Carnival in Venice which may have begun as early as the twelfth century, with masking traditions first recorded in the thirteenth century. That the festival was often seen as a threat to order by local authorities is reflected in Italy's many laws over the past several centuries attempting to restrict celebrations and the wearing of masks which are, of course, a central feature of the Carnival. Carnival celebrations in Venice ceased for many years after the city came under Austrian control in 1798, but were revived in the late 1970s.

Carnival in Portugal is celebrated throughout the country, most famously in Ovar, and Madeira. It was also introduced to the Cape Verde Islands by the Portuguese who settled there bringing along Catholic festivities and traditions to the uninhabited islands. The Portuguese also brought Carnival to their colony of Goa in India. Here the Carnival is known as 'Intruz' (from the Portuguese word Entrudo) and its most extensive observance takes place in the city of Panaji. Ironically, although Portugal introduced Christianity and the customs related to Catholic practice to Brazil, the country has begun to adopt some aspects of Brazilian-style Carnival celebrations, in particular those of Rio de Janeiro with their brilliant parades, samba music and other Brazilian performance forms.

Spain has a long and much varied tradition of Carnival celebrations. The most famous of these are in Cádiz, and Catalonia. In Cádiz, as in many Carnival traditions, the costumes often reflect recent events in the community or, increasingly, in the world. For example, during the bird flu epidemic in 2006, many revelers masqueraded as chickens. The Cádiz Carnival, like certain West Indian aspects of Carnival, is famous for the social commentary of its masqueraders such as the chirigotas, choirs, and comparsas. The chirigotas are well-known witty, satiric popular groups who sing about politics, new times and household topics, wearing the same costume, which they train for the whole year.

Catalonia has also developed a host of specific traditions within its Carnivals. Solsona's Carnival is one of the longest Carnivals in Catalonia; free events in the streets, and concerts every night, run for more than a week. The Carnival is known for a legend in which well-meaning townspeople attempting to help a donkey graze on some grasses growing atop a bell tower hoisted the animal up by its neck. To commemorate this story every year, people in Solsona hang a stuffed donkey from the tower. It then 'pisses' above the excited crowd by virtue of a water pump.

Carnival in the New World

The popularity and fame of the Parisian Carnival spread not only to other locales on the continent, but to the growing and increasingly wealthy colonies in the New World. In the 1770s the French colonies of Saint Domingue (now Haiti), Martinique, Guadeloupe, and Saint Lucia were on the rise, rapidly becoming sources of enormous wealth for France. This wealth, generated by slave labor on sugar plantations, lead to a colonial high society with plenty of disposable income and few of the pleasures of the Parisian metropole. Carnival emerged as an important pastime for the wealthy plantocracy who invested great sums in holding Carnival balls and masquerades. Participation by slaves was certain prior to emancipation, and they would have been present not only as servants but also often as musicians or performers. By 1783 the French and English had

become dominant forces in the Caribbean and, of course, in North America as well. As their empires expanded the Spanish empire diminished in the Caribbean archipelago.

Most of the islands in the Caribbean celebrate Carnival including the Dominican Republic, Antigua, Aruba, Cayman Islands, Curaçao, Barbados, Dominica, Haiti, Grenada, Jamaica, Saint Maarten, Saint Lucia, Saint Kitts, Saint Thomas, U.S. Virgin Islands, Saint Vincent, and the Grenadines which are all known for their Carnival seasons and unique celebrations. Probably the most famous and widely copied Carnival in the Caribbean is the Carnival in Trinidad. Originally a colony of the Spanish, the influx of French planters in the eighteenth century introduced Carnival to the island where it was primarily a white colonial affair. After the emancipation of the enslaved African population in 1838, however, the tone of the festival changed dramatically as more and more freed African-Trinidadians began to participate. A wide variety of Carnival characters and masqueraders evolved and bore evidence of not only African influences but also Indian influences after the arrival of indentured laborers from South Asia during the nineteenth and twentieth centuries. These characters developed slowly, often beginning as satirical reflections on people or issues in society, creatures from folklore or history or creative elaborations of French and other European Carnival figures. Other characters, like the 'Neg Jadin' or 'garden slave' were originally played by artistocrats pretending to be their own servants during Carnival. These portrayals were later taken on by emancipated Africans themselves in one of those role reversal performance traditions, like minstrelsy, so common in slave societies of the new world where the oppressed imitates the oppressors impression of him/herself. Along with the Neg Jadin there were the Dames Lorraine, the Burrokeets, the Clowns, Bats, Bears, Red and Blue Devils, Jab Jabs, Jabs Molassi, the Wild Indian bands, the Moko Jumbies (stilt walkers), the Midnight Robbers and later the multitudes of sailors and soldiers commandeering the streets and sidewalks from would-be onlookers. Each character had a unique costume and attendant performance style.

One of the masquerading traditions that horrified the upper classes the most was called the *pissenlit*. Literally the 'bed-wetter,' this piece of performance entailed a grown man sporting bedsheets or linens stained red in imitation of bloody menstrual rags. By the late 1930s and right through the 1950s and early 1960s, the sailor bands emerged as the most popular form of masquerade for the average (male) Trinidadian. Trinidadians had been imitating sailors since at least the nineteenth century when the British sailors began making regular calls at Port-of-Spain. But in the 1940s and 1950s, when Americans were stationed on Trinidad during the World War II, the sailor costume achieved the height of its popularity. Thousands of people wearing the basic white sailor outfit, some carrying talcum powder to spray on cringing spectators, would parade behind their favorite steelbands as they moved across the city. The Steel Pan (sometimes erroneously called the Steel Drum by non-Trinidadians) was invented in Trinidad and steelbands were deeply rooted in their neighborhoods and their followers were fiercely loyal to the music, the costume, and the home turf. When two steelbands, coming from rival neighborhoods met, break-out of pitched street battles, known as steelband clashes, were not uncommon. The steelbands, with glorious names like Desperadoes, Renegades, Red Army, and Invaders taken from American movies, advanced on the downtown in snaking columns of warriors holding banners that read "To Hell and Back" or "D-Day." Today much of that tradition exists on the margins of Carnival, with center stage being taken by large masquerade bands with hundreds, if not thousands of revelers in purchased costumes and dancing to prerecorded or live-performing soca bands. Increasingly, however, there has been a return to the smaller art form of masquerade with parody and social commentary at its heart. These endeavors have been pioneered mostly by local artists and musicians.

Carnival is an important cultural event on the Dutch Antilles islands of Aruba, Curaçao, Sint Maarten, Saba, Sint Eustatius (Statia), and Bonaire. Festivities on these islands in many respects parallel those of Trinidad with the exception that the J'Ouvert in the Dutch Antilles usually ends at sunrise with the burning of a straw King Momo, cleansing the island of sin and ill fortune. Humorously enough, on the island of St. Eustatius he is called Prince Stupid.

Carnival on the small island nation of Dominica has a variety of unique masquerade traditions, most strikingly in what is perhaps the oldest form of costume called the sensay. The name itself is most likely Ghanaian in origin and outfit itself is made of frayed rope and other fibrous material such as pounded leaves of the agave, and 'langue beff.' The material is tied around the body in layers so that it gives the effect of strips of monstrous plumage, which is, in effect, the West African source of this particular masquerade. In addition, a mask is worn on the face and cow horns form the headpiece. Sensay costumes are also made of strips of paper, cloth, frayed plastic sacks and dry banana leaves.

Carnival has also been celebrated in Cuba since the eighteenth century. After Fidel Castro's Communist Revolution, Carnival's religious overture was suppressed, however many of the events remained, existing with basic tolerance from the state. Carnival celebrations were in decline throughout Cuba from the 1960s, but have revived in recent years with an emphasis on the African cultural antecedents to the modern event.

In Haiti, Carnival or Kanaval exists alongside another tradition called Rara which brings in elements of the Haitian religion of Vodoun, itself deriving from belief systems in what is now Benin in West Africa. The Kanaval most likely derives from celebrations brought to what was then the sugar colony of Saint Domingue but, as in many Caribbean Carnivals, was radically altered and reshaped by Africans after the successful rebellion of 1804 which gave Haiti its independence.

In the modern era a sort of reverse colonization has developed as a result of the decolonization of the Caribbean in the 1960s.West Indian migrants to the United Kingdom, Canada, and New York, for example, have brought with them the traditions of the Carnivals of Trinidad, Haiti, and the smaller islands. The Carnivals now celebrated at Notting Hill, London, and Brooklyn, New York, however are not tied to the religious calendar of Catholicism. Taking place mostly in the late summer, such events as Caribana are what might properly be called 'ethnic display events' in which Caribbean culture is the featured element.

Carnival is celebrated in New York City in the borough of Brooklyn. As in the UK, the timing of Carnival has been

separated from the Christian calendar and is celebrated on Labor Day Monday, in September. It is called the West Indian American Day Parade or West Indian Day Carnival, and was founded by immigrants from Trinidad. The West Indian Day Carnival is one of the largest parades and street festivals in North America with approximately one million people participating or attending. The parade, which consists of steel bands, floats, elaborate Carnival costumes and sound trucks proceeds down Brooklyn's Eastern Parkway in the Crown Heights neighborhood.

The best-known, most elaborate, and most popular Carnival events in the United States are in New Orleans, where it is commonly referred to as Mardi Gras (Fat Tuesday). The New Orleans Carnival season begins after Twelfth Night, on Epiphany (January 6). It is a festive time of parades, balls (some of them masquerade balls), and 'king cake' parties. It has also been part of the winter social season for elite families at which time young women were 'presented' at débutante balls. The parades in New Orleans are organized by Carnival 'krewes.' Krewes select a Carnival king, known as Rex, and build elaborate floats. Riders atop the floats toss 'throws' such as strings of plastic colorful beads, doubloons (aluminum or wooden dollar-sized coins usually impressed with a krewe logo), decorated plastic throw cups, and small inexpensive toys.

Latin America

In Mexico, Carnival is celebrated in many cities and towns, most notably in Mazatlán, Sinaloa, Mérida, Yucatán, and in the city of Veracruz, where Carnival is celebrated with traditional music, folklore, arts, and dances. People dress in bright, feathered costumes resembling the indigenous traditions, and create a series of performances on the streets as well as on stages. In most cases there is a large set-up of fair games and roller coasters. In Bolivia, Chile and Peru La Diablada has been named a Masterpiece of the Oral and Intangible Heritage of Humanity by UNESCO. It is an essential aspect of Carnival in the Bolivian highlands and is marked by performers wearing intricate and colorful devil masks and costumes. It is the result of cultural traditions deriving both from the Spanish and indigenous Andean peoples.

The Carnival in Brazil is perhaps the most famous Carnival in Latin America, if not the world. It has its roots in the seventeenth century and is celebrated throughout the country. The most iconic expression of the Brazilian Carnival takes place in the Carnival in Rio de Janeiro, with samba schools parading in the Sambadrome (an vast stadium built in 1984 to host Carnival processions and allow viewing by mass numbers of spectators). It's the largest Carnival event in the country, and one of the largest in the world. Blocos organize community members or neighborhoods into themed samba groups accompanied by music (Bandas). There are more than 440 blocos in Rio de Janeiro.

Approaches to Carnival

Carnival is generally experienced as a chaotic, confused, and disorienting time. All the comforts of time and place tend to evaporate in a gross assault on the senses. Reason flies away. This goes as much for the scholarly interpretations of the event as for the event itself.

One often reads of Carnival as a form of resistance or, conversely, as a 'steam valve' manifesting as an allowable expression of discontent permitted by the powerful within rigidly defined social hierarchies. One may also find interpretations of Carnival as a key feature of some primordial identity suddenly threatened by commercialism, political patronage, and corruption. It is both full of profound meaning and profoundly meaningless. What accounts for this diversity of views and the denial of this diversity by many scholars?

Historically the focus on Carnival by scholars has been guided by political agendas and a woeful lack of theoretical reflection that explains the too frequent dismissal of ambiguity and contradiction in the Carnivals. The Carnival is subject to numerous forms of reductionist analysis. That is to say that many scholars are eager to demonstrate just how Carnival is a form of resistance, or hopelessly distorted by political manipulation and commercialism, or an assertion of identity that should be good for development, or the exemplar of resistance through the reversal of social strata, etc. Social scientists, historians, and writers have analyzed Carnival from a variety of perspectives often examining how the social and political contexts affect the ways in which Carnival occurs as well as the dynamics of race, gender, and class that characterize Carnival. Carnival performance has been placed at the center of a 'national culture' and given the burden of fulfilling hopes generated by an ardent nationalist rhetoric.

Judging by the literature, Carnival can be both a 'Bread and Circuses' kind of mass distraction and an occasion for political action and defiance of authority. The most illuminating analyses of Carnival take the greatest care to identify and trace the implications of political manipulations and social transformations. They socially ground and locate the controversies and the stakes involved in the debate over the festival's form and meaning. For instance *contra* the idea that Carnivals may be inherently oppositional, Stallybrass and White (1986: p. 19) suggest that nostalgia, uncritical populism, and licensed complicity are common errors in cultural nationalist or biased analyses of Carnivals.

One common way of understanding is to see it as the "collective expression of the perceptions, meanings, aspirations, and struggles engendered by the material conditions of social life and informed by the cultural traditions of the group" (Lee, 1991: 417). Another common approach to the analysis of Carnivals is to examine controversies over the nature of a group's cultural heritage that arise during the Carnival season (Cohen, 1993; Gallaugher, 1995; Green, 2007). The most important issues raised consider exactly whose culture is presented as either the national or ethnic culture. In these studies Carnival is an important platform in which cultural conflicts are expressed. Controversies about culture during Carnival tell various ethnic groups about themselves and their 'cultural citizenship.'

Finally, many contemporary studies of Carnivals place them within the broader context of the political economy of identity. Key to such a project is an understanding of the ways in which local and global histories are interwoven. For example, the Carnival in Trinidad and those in England, the United States,

Canada, and other parts of the Caribbean, are aspects of the processes of cultural change in the 'metropole' and in the 'periphery.' Yet, to prioritize either of these locations is to lose sight of the active and on-going relationships those so-called core locations and peripheral ones have been involved with for centuries. The histories of all of the Carnivals under consideration here occur as a result of similar, sometimes the same processes. The particular configuration that any Carnival may take and the role it may play in the lives of those who participate in it and those who do not depend upon the particular conjunctions of class, gender, ethnicity, and generation as well as broader structures of community and nation found in each locale.

This approach might be characterized as a kind of political economy of identity that compels one to consider the place of 'class, capitalism, and power' in the constitution of localized subjects, yet can also account for subjects who may occupy multiple localities as can be argued in the case of the transnational communities. In that regard scholarship cannot separate the analysis of cultural identity, cultural practices, and cultural change from an analysis of work, power, and politics. The key factors informing these analyses include shifting labor markets and immigration policies, struggles for political recognition, economic autonomy, and cultural legitimacy. Ideally, scholarly approaches to these festivals will locate the social and cultural phenomena of the Carnivals within an analysis of the conditions of existence of those who make it, watch it, experience it, and talk about it within particular historically constituted structures of power and representation that influence those activities (Roseberry, 1988).

There is increasing recognition of the futility of reducing Carnival to any singular kind of entity with universally realized qualities and attributes. What development bureaucrats, corporate sponsors, political functionaries, culture ministers, folks on the street, and scholars may speak of when they use the term Carnival, may be quite different from one another. What any one of these figures may argue is the 'true essence' of the Carnival must be situated within any number of political, economic, and even cultural projects. The invocation of 'the Carnival' calls forth idealized images of resistance, the assertion of identity, of national pride and struggle that resonate in myriad ways for different peoples each engaged in located struggles for economic autonomy, cultural integrity and respect, and political power. The work of anthropologists, ethnomusicologists, art historians etc. demonstrates the polysemic nature of the Carnival as a socio-, cultural, economic phenomenon. The event is composed of numerous events and activities none of which may be said to be of greater importance than another. Whatever these Carnivals may be they are the products of histories, a manifestation of social tensions, a barometer of cultural change, and a crucible for creating, discovering, and asserting identities. The Carnivals encompass contradictory ideas and practices. People in position to assert their visions of what the Carnivals are seek to extinguish or at best minimize alternative interpretations and activities by rewarding those representations and practices that conform with their vision and by punishing or condemning those that do not. That in itself is part of the masquerade.

Abstract

Julio Caro Baroja was one of the founding fathers and most influential figures in Spanish social anthropology and cultural history during the Franco years and the *transición*. Veering between Madrid and the Basque Country and Navarre and defending a liberal agenda he always kept a distance to the Franco regime and its academic supporters. Caro Baroja's academic career opportunities were severely limited because of his opposition to the Franco regime and because he spoke out against its isolationist policies. This was also the main reason why he opted out of academia to become an independent scholar. However, the distance from official institutions would not diminish the role and the impact his writings had on shaping modern Spanish social anthropology and cultural history.

Introduction

Julio Caro Baroja (1914–95) was one of the founding fathers of Spanish and Basque anthropology. His work comprises over 30 books and numerous book chapters, contributions to academic journals, newspaper, and magazine articles, not to speak of the many essays he wrote for exhibition and museum catalogs. Marginalized as an academic and intellectual during the Franco dictatorship, his liberal-pluralist views – which also marked his scholarly work – served as a much valued counterweight against the powerful Spanish nationalist cause and its 'academic' use of folklore and traditions. Although working as an independent scholar for most of his life, his writings became an important point of reference in anthropological discussions particularly during the transitional years that followed the death of Franco. Today his impact is still detectable. His work is cited with regular frequency. Some of his books have even achieved the status of modern classics. One of Caro Baroja's greatest lasting legacies as an anthropologist is perhaps the fact that the various cultures of the Iberian peninsula are now studied without resorting to the rhetoric of race, biological explanations of ethnicity, or narrow nationalist interpretations of culture.

Caro Baroja's writings do not fit easily traditional academic labels or descriptions. It veers between a cultural anthropology that is reminiscent of Franz Boas's work but also contains detailed ethnographic descriptions and biographical accounts. On occasion, Caro Baroja's work pays homage to intellectual traditions and paradigms that seem nowadays somewhat dated, such as the German–Austrian dominated *Kulturkreislehre*. However, it can be argued that Caro Baroja always managed to stay away from unthinking applications or anything that smelled of theoretical dogma. While some of his oeuvre has been translated into other languages, his work continues to be studied mainly by Spanish-speaking anthropologists or cultural historians who have an interest in the pluralistic cultural landscape of the Iberian peninsula. Impact and influence there certainly was, but Caro Baroja's writings deserve to be mined and to be critically evaluated beyond those interested in Spanish-speaking anthropology. In particular, scholars interested in cultural sociology and cultural history will find in Caro Baroja's work much to appreciate.

Education and Training

Julio Caro Baroja was born in 1914 in Madrid. His father was a well-known publisher and his mother played an active role in Madrid's cultural scene. His uncle, the writer Pio Baroja, would also exercise a considerable intellectual influence over him. For most of his life, Caro Baroja commuted between the two family homes in Madrid and Vera de Bidasoa, in the north-eastern part of Navarre that borders on the Basque province of Gipuzkoa. The fact that Caro Baroja was brought up in Madrid and in the Basque Country and Navarre would shape and influence his academic career and his later life choices considerably. He first studied ancient history at Complutense in Madrid but his studies were interrupted by the Spanish Civil War. After a longer spell in Itzea, the residence of the Baroja family in Vera, he eventually returned to Madrid to resume his studies in 1939 and 3 years later was awarded a PhD in history for his thesis 'Traditional cults and rituals in Spanish folklore.' Caro Baroja had been extremely lucky in having been considered unfit for military service. Not being drafted meant first and foremost avoiding potentially challenging situations. As an intellectual, bookworm, or 'egghead' – in Francoist Spain these things were interchangeable – Caro Baroja would have aroused all kinds of comments from both superiors and 'comrades.'

Even before achieving academic distinction, Caro Baroja had already two longer book-length studies in anthropological journals to his credit. He was seen as a promising young student and over the course of two summers in 1930 and 1931 he became part of the pioneering excavating effort of a group of Basque archaeologists and social anthropologists under the leadership of José-Miguel Barandiaran and Telesforo de Aranzadi, the founders of Basque anthropology. From Barandiaran he learned about Malinowksi, Durkheim, and the Durkheimians. At the university he was in close contact with Ortega y Gasset who introduced him to the work of Wilhelm Schmidt, one of the exponents of the then fashionable theory of cultural cycles and cultural areas, and to the biological and early environmental models of Jakob von Uexküll. There were also other academic visitors from Germany, such as Hugo Obermaier and Herman Trimborn, who spent considerable time in Madrid and from whom Caro Baroja learned 'the tricks of the trade.' After having graduated, he worked first as an assistant in the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61172-8

Department of Ancient Spanish History and Dialectology and Popular Traditions at the University of Madrid. Later this activity partly overlapped with his serving as the Director of the Museum of the Spanish People, a position which he held from 1944 until 1954.

As a young academic and subsequently in his administrative role as director, Caro Baroja was part of the intellectual scene in Madrid, or at least what was left of it after the Civil War. Being a liberal-minded young man who had sympathized with the republic but who also tended to avoid the extreme choices that many in the crisis-ridden Spanish Republic seemed to prefer, he tried to hang on if not to a publicly declared liberal agenda (something that was impossible at the time) then at least to some sense of free academic thinking. For example, in his role as academic expert and director of the anthropological museum, he led various efforts against the isolationist policies of the Franco regime and its devastating effects on academic life. He played host to visitors and became an important informant to those who had an interest in the cultures of the peninsula: among them were George M. Foster from the Smithonian, Walter Starkie, the Director of the British Institute in Madrid, and Julian Pitt-Rivers from the University of Chicago who conducted field work in Andalucia and who greatly valued Caro Baroja's advice and support.

Caro Baroja's growing interest in French, English, and American anthropology was against the grain of much that Madrid's social and political elite were thinking at the time. Particularly during the Second World War his growing international network aroused some suspicion. His contacts with the Smithsonian and the anthropologist Pitt Rivers, the British Council, and Walter Starkie were subject to the authorities' scrutiny. Later, during the Cold War the new relationship between the Western Allies and Franco's regime made it possible for him to visit the United Kingdom (in 1951) and the United States (in 1952) where he met Evans Pritchard and Alfred Kroeber, respectively – a rare visit for a Spanish scholar in those times. Despite his international leanings, Caro Baroja remained skeptical about any particular schools of thought or anthropological paradigm. His interest and training in history made him more receptive toward cultural history and what could be described as a cultural anthropology of the Boas type.

The Study of Culture Applied to the Iberian Peninsula

In 1949a, Caro Baroja published *Análisis de la cultura: Etnología, historia, folklore* (*Cultural Analysis: Ethnology, History, Folklore*). The text was based on lectures given in Barcelona in 1946. In the book the author paid reference to the German and Austrian cycle-of-culture approach, British functionalism, and American cultural anthropology – but also Durkheim and the anthropological agenda that followed the Durkheimian approach; he even discussed linguistic approaches like that of de Saussure. However, we can also see where Caro Baroja differed from all these paradigms by insisting on the materiality of culture(s) and its historical dimensions. The final part of the book discussed a number of examples ranging from folklore to ethnography, which threw light on what the author meant by 'materiality of culture.'

In contrast to American anthropologists like Boas or Kroeber, Caro Baroja also maintained a strong interest in the study of individuals and distinguished characters. It was not so much that he admired charismatic personalities but rather that the study of some individuals almost functioned like a prism. He was not so much interested in individuals or individualism per se but in the plasticity and variety of cultural and social life. Sometimes, he argued, the particularities of historical and cultural change were better studied by looking through the lens of an individual's life and work than studying larger social groups or subpopulations; in any case, the two perspectives should not be regarded as being mutually exclusive but should help to enrich our understanding of social and cultural life.

The same year *Análisis de la cultura* was published saw also the publication of Caro Baroja's most important work, *Los Vascos* (*The Basques*). A few years earlier he had already made some important inroads into the study of Basque culture. His first publication had been *Tres estudios etnograficos relativos al País Vasco* (*Three Ethnographic Studies Related to the Basque Country*) (1934), a presentation of the findings of his work with Barandiaran and Aranzadi. This was followed by an impressive output over the next few years: *Los pueblos del Norte de la Peninsula Ibérica* (*The Northern People of the Iberian Pensinsula*) (1943), *La vida rural en Vera de Bidesoa* (*Rural Life in Vera de Bidesoa*) (1944), *Los pueblos de España* (*The Peoples of Spain*) (1946), and *Materiales para una historia de la lengua vasca en su relación con la latina* (*Documents for a History of the Basque Language's Relation to Latin*) (1946).

While *Los pueblos del Norte* and *Los pueblos de España* were more comparative in outlook, the other titles obviously addressed the social and cultural conditions of the Basque country and Navarre, including the rural community in Vera, which he increasingly considered to be his home. As he confessed in an autobiographical account many years later, he liked Madrid as a city that would always remain associated with his childhood and youth but he was not a 'castillanista.' Particularly during the bleak years in which the Franco regime consolidated its power, Madrid seemed often rather monoglot and one dimensional. In contrast, small-town life in Vera, Navarre, and the nearby cities along the Basque coast appeared to be more varied and full of life and stories.

Many of Caro Baroja's Basque writings would become testimonies to the rich small-town and rural life in the Basque Country and Navarre – an argumentation that was directed against the all-too-common perception that it was only cities which provided excitement and a colorful life, while the countryside by definition had to be dull and monotonous. Spending long periods in Vera held also the major attraction of conversations and travels with his uncle Pio Baroja and an exposure to a different kind of learning that included the reading of the humanist classics. His uncle's library provided Caro Baroja with a second, humanist education, which was very much in contrast to his 'official' student years. This second education had the advantage of the student being able to choose his own curriculum and to read at his own pace, and according to his own humanist preferences. Some of the titles Caro Baroja read were in the language in which they were originally written. His Latin was certainly above average. He also mastered Italian, Portuguese, French, and some German. His English was passable but, by his own admission, far from

perfect – so that he would always try to improve it. His knowledge of Basque was certainly good enough for reading purposes and for basic communication, an astonishing achievement for somebody who had not been raised in or constantly exposed to the Basque-speaking environment.

Like the other studies which preceded it, *Los Vascos* appears to be remarkably restrained in terms of sympathizing with any particular anthropological approach or paradigm. In the introduction to the book, the author makes allusions to environmental and functionalist approaches of the cultural cycles type; however, in the same introduction, the author also states that society needs to be studied as a totality and that it would be wrong to single out one particular function or cultural cycle over any other. To compartmentalize would limit our understanding. Caro Baroja's notion of functions seems particularly interesting. His unique historical method does not see some primordial function as being specific to a particular past period or an earlier cycle but sees functions rather as having been part of a cultural inheritance that shaped and continue to shape the present in particular ways, yet without making that society totally path dependent on such functions.

It is the openness to change and modification which is most interesting in Caro Baroja's observation of cultures. In particular it is the unique combination of structure/function *and* openness that marks Caro Baroja's 'liberal' anthropology of the Basques and which also contributes to a rejection of the false alternative of universalist versus nationalist-particularist values and perspectives. From there it was but a short step to argue that culture as a concept should be given clear preference over concepts such as 'race,' 'ethnic belonging,' 'homogeneous people,' or 'national communities.' Thus, *Los Vascos* could be considered as a rejection of, and a rupture with, essentialist concepts and theories. Instead, Caro Baroja's study offered thick descriptions of cultural configurations, each of which alluded to some particular cultural and human geographical context and function, such as the countryside, the sea, and different types of human settlements like the *auzola* (community neighborhoods), village, or town. Retrospectively it appears almost as if *Análisis de la cultura* provided the theoretical scaffolding, including discussions of examples of what and what not to do, while *Los Vascos* became the free-standing edifice that remained after the theoretical scaffolding had been removed.

In 1954 Caro Baroja experienced a personal crisis after a string of deaths in the family. The Baroja family had always consisted of distinguished characters who contributed to the arts and to public life in general, even under the difficult circumstances after the Spanish Civil War. The death of his mother in 1950 followed by his two uncles, Ricardo in 1953 and Pio in 1956, was experienced by Caro Baroja as a huge loss. He felt increasingly isolated and without intellectual and social support. Never an admirer of academic life and even less a fighter interested in achieving academic distinction for its own sake, but also tired of the increasing isolationist positions of the Franco regime which made his international contacts look increasingly suspicious and a one-man affair, he resigned from all academic and administrative positions. His financial independence, secured by the royalties of his uncle's literary legacy and his parents' inheritance, allowed him to continue to work as an independent scholar without the burden of academic duties and responsibilities and without running the risk of becoming politically suspect.

From Spain to the Sahara and Back

It was anthropological curiosity but perhaps also the chance to escape from the pain caused by the death of his beloved mother that made Caro Baroja embark on something totally different. Known to the local colonial authorities and partly supported by them, Caro Baroja spent some periods in 1952 and 1953 in the Maghreb and in particular what is known today as Western Sahara. To be sure, Caro Baroja was not the first to study Sahauri culture, and like its French or British counterpart the Spanish colonial power (or what was left of it after the loss of Cuba and the Philippines in 1898) showed some interest in the anthropologist's field work, particularly when it came to information concerning language, local customs, and traditions. Conducting fieldwork, Caro Baroja used a translator, which naturally limited his scope of understanding. Still, the field work and investigation allowed for some fascinating insights into Sahauri nomad culture, as the two publications *Estudios saharianos* (*Sahauri Studies*) (1955) and *Estudios mogrebies* (*Maghreb Studies*) (1957) clearly demonstrate. For the author, these studies constituted something new because for the first time he had left familiar terrain and the intellectual comfort zone to study a culture which was clearly distinct from anything he had observed before.

It would be mere speculation to say that there is a straightforward link between studying Sahauri and Maghreb nomads and returning to Spain to study outsider cultures of the Iberian peninsula. However, one might wonder about the connection between the two preoccupations because over the next two decades Caro Baroja dedicated significant time writing about those who did not fit easily into what was considered to be a homogeneous Spanish culture: witches, Jews, and non-Christian practices and practitioners. *Los Brujas y su mundo* (*Witches and Their World*) (1961) became, after *Los Vascos*, his most famous study. It was followed by *Vidas magicas e inquisición* (*The Lives of Magicians and the Inquisition*) (1967) and *Inquisición, brujería y criptojudaismo* (*Inquisition, Witchcraft and Crypto-Judaism*) (1970). Earlier, in *Razas, pueblos y linajes* (*Races, Peoples and Lineages*) (1957) Caro Baroja had already argued that the concept of race was of little or no value. He also argued against the officially supported view that Jews played no role in Spanish culture in his three-volume study *Los judios en la España moderna y contemporanea* (*Jews in Modern and Contemporary Spain*) (1962).

That the cultures of the Iberian peninsula were not as unitarian as Francoist ideology reaffirmed was a constant theme in Caro Baroja's work and culminated in a critical study which openly challenged the official ideology, *El mito del carácter nacional* (*The Myth of National Character*) (1970). Some of Caro Baroja's work about customs and folk traditions looked at the rich pagan traditions that prevailed in the midst of Christian Spain, another proof that Spain was not one homogenous cultural entity as Francoist cultural policies claimed. *El carnaval* (*The Carnival*) (1965), *La estación de amor* (*The Season of Love*), *El laberinto vasco* (2003), and *El estío festivo* (*The Festive Summer*) (1984) are all thick descriptions of local or

regional festive days and celebrations, which challenged the hegemony of Catholic dogmatism and its political-cultural usages. Obviously Caro Baroja continued to follow in the tracks of his atheistic uncle Pio Baroja. However, in contrast to his uncle, the agnostic social anthropologist nephew continued to show a deep interest in the cultural-anthropological dimensions of both pagan and Christian celebrations as is evident from studies like *Las formas complejas de la vida religiosa* (*Complex Forms of Religious Life*) (1978), *De la superstición al ateismo* (*From Superstition to Atheism*) (1974), and *Ritos y mitos equivocos* (*Rites and False Myths*) (1974).

The Study of Basque and Navarrese Culture

Despite his move into other themes and areas, there remained for Caro Baroja an intellectual homeland to which he would return time and time again – the study of culture of the Basque Country and Navarre. Particularly from the early 1970s onward, his output amassed to what looks now like an impressive number of books, the multivolume sets *Etnografía historica de Navarra* (*Ethnografic History of Navarre*) (3 volumes) (1972) and *La casa en Navarra* (*Homes in Navarre*) (4 volumes) (1982), and the series *Estudios Vascos* (*Basque Studies*) (18 volumes) (1973–1988) being the most visible signs. What was new, however, but which did not come as a total surprise if one thinks about Caro Baroja as a committed liberal, was what could be called an 'individual' or 'subjective' turn in his work. This is most visible in his family portrait *Los Baroja* (*The Barojas*) (1972) and the two essay collections *Biografías y vidas humanas* (*Biographies and Human Lives*) (1986) and *Los hombres y sus pensiamientos* (*Men and Their Thoughts*) (1989).

The most distinct study of this later phase in Caro Baroja is his impressive *Los Vascos y su historia a través de Garibay* (*The Basque and Their History according to Garibay*) (1972), a study of the Mondragon chronicler and educator Esteban de Garibay (1533–99), who spent most of his life between the Basque Country and Navarre and Madrid. In the final chapter of the book it is evident that this veering and intellectual traveling between the Basque lands and the capital constituted a kind of Barojaian hermeneutic cycle, which allowed the social anthropologist and cultural historian to gain a unique perspective and observation point, which in turn allowed him to gain distance from both Spanish and Basque nationalisms.

It was such critical distance and perspective that not only informed his late writings on the profession itself, like *La aurora del pensamiento antropológico* (*The Golden Age of Anthropological thinking*) (1983), *Los fundamentos del pensamiento antropológico moderno* (*The Foundations of Modern Anthropological Thought*) (1985), and *Las falsificaciones de la historia en relación con la de España* (*Historical Falsifications in Relation to Spain*) (1991) but also allowed for some genuine insights into what it meant to be Basque, Spanish, or both. It was in thought-provoking essay collections such as *Terror y terrorismo* (*Terror and Terrorism*) (1989), *Ser o no ser vasco* (*To Be Nor Not To Be Basque*) (1998), and *El laberinto vasco* (*The Basque Labyrinth*) (2003) in which Caro Baroja's liberal thinking truly found its mature expression and through which he became known to a wider audience, almost to such an extent that he turned into a public intellectual (which is perhaps a bit of a misnomer since the label does not honor his wish for a quiet and private life, preferably in his retreat in Itzea). The essay was the most ingenious, explorative, and experimental form which allowed Caro Baroja to think about the complications of what it meant to be or not to be Basque.

Caro Baroja remained active and continued to publish until his death in 1995. Late acknowledgment came not only in the form of awards, prizes, and Festschriften but also in the form of increased academic praise and acknowledgment. The historian Juan Pablo Fusi called him 'the most important personality of contemporary post-war Spanish historiography,' and the renowned American anthropologist William A. Douglass considers the works of 'Don Julio' and particularly *Los Vascos* to be classics in the field. Such praise seems justified. Particularly Caro Baroja's Basque writings constitute an invaluable body of work indeed. Not only anthropologists but also cultural sociologists and cultural historians have come to rely heavily on Caro Baroja's findings and will, predictably, continue to do so in the future. His most important contribution, however, still consists in having considerably shaped the modern anthropological discourse in Spain, particularly in the difficult times of the Franco regime and then later during the Spanish *transición*. That Spanish and Basque social anthropology today avoid the use of concepts such as 'race,' or making dubious references to blood types or genetic differences, is not at least due to Caro Baroja's subtle influence. He not only argued for another, more culturally oriented anthropology but also led by example, as can be seen in his most important work such *The Basques* or his book about Garibay.

Abstract

Catton defines carrying capacity as the maximum persistently supportable load of a focal population in a bounded environment. Here, definitions of carrying capacity for natural populations, ecosystems and humans, as well as biocapacity, are presented, with issues fully discussed pertaining to their proper interpretation, models and estimation, debate and derived paradoxes. With the explosion of the human population, the threat of overstepping the earth's carrying capacity has become a sword of Damocles, hanging over humanity and urging it to choose a sustainable path of development. Carrying capacity has become arguably the most important concept in the era of Anthropocene.

Humans are fascinated by growth dynamics, from the weight of an infant to the size of an economy. Two intrinsic questions on any growth dynamics are how fast and how long the system can grow. That is, the rate and the bound of growth. An unbounded growth is infeasible due to limited resources, and carrying capacity is a measure of this limitation. In 1798, Thomas Malthus proposed an exponential growth curve in his *Essay on the Principle of Population*, stating that a population with constant fecundity greater than its mortality will grow exponentially till it causes inevitable conflicts with the limited supply of resources. Deminishing resources and the expanding population will inevitably lead to scramble competition. Malthus's idea has further inspired Charles Darwin to adopt resource competition as one prerequisite of evolution via natural selection. Darwin said in his *Autobiography* that, "I happened to read for amusement Malthus on *Population* and being well prepared to appreciate the struggle for existence which everywhere goes on from long-continued observation of the habits of animals and plants, it at once struck me that under these circumstances favourable variations would tend to be preserved, and unfavourable ones to be destroyed. The result of this would be the formation of new species." Such struggle of life will ensure only the survival of the fittest, or equivalently as Russel Wallace put, the elimination of the unfit. Such a density-dependent mechanism of population regulation that intense competition happens when resource demand approaches supply was formally formulated by Pierre Verhulst in 1838, by adding a parameter K into the Malthusian equation to curb the unbounded growth. This equation is now well-known as the logistic equation, and the parameter K the carrying capacity.

Population Carrying Capacity

Catton (1986), defined an environment's carrying capacity as its maximum persistently supportable load. In ecology, carrying capacity is normally defined as the maximum population of a given species that can be supported indefinitely in a defined habitat without permanently impairing the productivity of that habitat (Rees, 1992). The concept of carrying capacity is rooted in the logistic equation depicting population dynamics under simple density-dependent regulation and has been developed across different hierarchical levels of living systems and in many sectors of human society (Seidl and Tisdell, 1999; Monte-Luna et al., 2004). In the Malthusian equation, the probability that an organism will reproduce or die is assumed to remain constant and is independent of the density of the population. Obviously, this can only be true when there is no competition among the individuals, normally when the population density is low. The growth of any population in a limited environment will eventually halt due to the shortage of resources. When the demand of the existing population on the resource (i.e., the population size times the basic per capita resource consumption rate required for maintaining life) is equal to the rate of resource supply, the population will reach its saturation level. This saturation level is decided by both the resource supply and the per capita resource consumption rate, called the carrying capacity of the environment for the focal population. Using the language of differential equations in mathematics, the Verhulst logistic equation reads as follows:

$$\frac{dN}{dt} = rN\left(\frac{K-N}{K}\right)$$

where N is the population size; dN/dt the derivative of population size, indicating the change rate of the population size; r the intrinsic population growth rate, indicating how fast the population can grow at small size; K the carrying capacity. The Malthusian equation only includes the first part of the right term, $dN/dt = rN$, meaning that the population change rate is proportional to its current population size. It also means that the per capita rate of increase $(dN/dt)/N$, often an indicator of population fitness, is a constant and thus density independent. In the logistic equation, the per capita rate of increase, $r(K-N)/K$, is a declining function of current population size N, thus becoming density dependent. In **Figure 1**, we can clearly see the difference between Malthusian's exponential growth curve and the saturation form of the logistic equation. Clearly, when K approaches infinity, the logistic equation becomes the

Figure 1 An illustration of population dynamics governed by the Malthusian equation and the logistic equation. Parameter values: $r = N_0 = 1$ and $K = 1000$.

Malthusian equation. The exact solution to the logistic equation exists,

$$N(t) = \frac{K \cdot N_0 \cdot \exp(r \cdot t)}{K + N_0(\exp(r \cdot t) - 1)}$$

where N_0 is the population size when time $t = 0$. When time t increases, the population size will converge to the carrying capacity K (**Figure 1**). The logistic equation is the simplest model, which contains a carrying capacity for the population. In fact, carrying capacity exists in many models that implement the negative density-dependence term, i.e., $(dN/dt)/N$ is a declining function of N.

Because the carrying capacity is also the asymptote, or the equilibrium of the population size in the logistic equation, the concept of carrying capacity has often been confused with population equilibrium, leading to unnecessary confusion and so-called paradoxes. In practice, many studies have considered the maximum population equilibrium or maximum population size as the carrying capacity, making the distinction even muddier. In 1969, Richard Levins hypothesized that if r in the logistic equation is negative, then we will have a positive dN/dt when $N > K$ and thus the population size will increase indefinitely. This is clearly counterintuitive. Although constraining r to be only positive can make Levins' paradox disappear, many declining populations are indeed experiencing the situation of $r < 0$, thus such a constraint could exclude many biologically meaningful scenarios. Although constraining r and K to be the same sign could resolve Levins' paradox, such a constraint nonetheless incurs a new problem on the meaning of negative carrying capacity ($K < 0$). The negative carrying capacity could be a measure of just how unfavorable the environment is (Hui, 2006). An important finding from metapopulation theory is that the source–sink dynamics are such that where a local population is in a 'sink habitat' a positive equilibrium can still be maintained due to contributions from migrants from source populations. These sink patches have a negative carrying capacity but support a positive population equilibrium. Clearly, the carrying capacity of a sink habitat is not equal to the maximum population equilibrium that can survive through the inflow of propagules, known as the rescue effect. This highlights the difference between carrying capacity and the maximum population equilibrium. Indeed, many preindustrial cities often benefited from being the hub of trade routes and supported a large population beyond their capacity.

In 1992, Lev R. Ginzburg considered incorporating additional mortality into the logistic equation without changing any other aspects of the environment. One of his proposals is: $dN/dt = rN(1 - N/K) - \mu N$, where $\mu N(\mu > 0)$ is the additional mortality term. As the resources do not change in this hypothetical scenario, intuitively the population with higher mortality might attain the same K, but only slower. However, the new population equilibrium is $K(r - \mu)/r(\mu < r)$, lower than the carrying capacity K. Once again, the Ginzburg paradox is due to the confusion between the concept of carrying capacity and population equilibrium. To illustrate, let us consider a thought experiment (Hui, 2006). There are three eggs in a six-position egg box (**Figure 2**). If we eat one and then put a new one in it everyday, the size of the egg population will be maintained at three. Now what is the carrying capacity of this egg population, three or six? Now, if we eat two eggs per day, the population equilibrium will become zero but the carrying capacity remains six. According to our knowledge, the above equation does not have any mechanistic problem but has been widely used as a theoretical foundation in spatial and metapopulation ecology. This new stable equilibrium is called the local carrying capacity of a metapopulation, whereas other scientists call this equilibrium local density. Once again, the concept of equilibrium was confused with carrying capacity. This confusion also appears in some textbooks, yet many others do differentiate between these two concepts. The carrying capacity of the egg box example should be the 'environment's maximal load,' i.e., the six positions in the egg box, and the equilibrium of egg population is three if we eat one and add one per day. If we can clarify these two concepts: carrying capacity and population equilibrium (Hui, 2006), there is no contradiction between intuition and there should be no Ginzburg's paradox.

Ecological carrying capacity is a measure of the amount of renewable resources in the environment in units of the number of organisms these resources can support. Normally, K is a function of both the species and the environment, and is expected to change only in evolutionary time (Daily and Ehrlich, 1992).

Figure 2 A population of three eggs at the equilibrium in an egg box with the six-holder carrying capacity.

Rees (1992) suggested that carrying capacity is the number of individuals of a given species that a given habitat can support without being permanently damaged. If the population of a given species exceeds the carrying capacity of a given habitat, then either the resources required to meet the needs of that species will be depleted, or the wastes produced by that species will build to the point of poisoning members of the species, or both, and the population will crash. In livestock management, carrying capacity is affected by many factors, such as habitat, climate, vegetation, soil profile, food quantity and quality and accessibility, inter- and intracompetition, foraging, parasitism, diseases, population density, social behavior, and anthropogenic disturbance. In terms of nutrition intake, carrying capacity has been defined as the accessible and utilizable energy in the habitat divided by per capita energy consumption (Ayllon et al., 2012). In terms of space, carrying capacity is also affected by aggregation or social group behavior, group size, dispersal distance, and habitat suitability, and can be defined as the amount of habitat available divided by the expected individual territory area for a given life stage (Ayllon et al., 2012). It is closely related to subsistence density, tolerance density, security density, maximum harvest density, minimum impact density in livestock and wildlife management (Hobbs and Hanley, 1990).

Carrying capacity is not a static number but is affected by the abundance and distribution of limited resources and by how individuals compete for these limiting resources (Ayllon et al., 2012). This notion is especially relevant in organisms that compete via both exploitation and interference because of behavioral responses, such as competition avoidance, induced by aggressive interactions typically result in a much reduced exploitation of the limited resource than could be accounted for by resource depletion alone (Ayllon et al., 2012). In territorial species, the behavioral adjustment of the size and shape of territories has profound consequences for their population regulation, demography, and spatial ecology. In practice, carrying capacity is determined by the resource in the least supply, 'the weakest link' as it were. For production purposes, accurate estimation of carrying capacity will affect the maximum sustainable yield, which is thought to be obtained when the population is maintained at half of the carrying capacity (Ayllon et al., 2012). By contrast, in conservation efforts, the maximum carrying capacity is the desired target.

Carrying Capacity of Ecosystems

The directionality of community succession is a powerful concept for conservation biology, analogous to the irreversibility of time in physics, and has revolutionized the understanding of complex adaptive systems. By definition, succession is 'an orderly process of community change' after disturbance. Knowing the directionality of succession is necessary for (1) distinguishing new from mature communities (i.e., defining the age of a community), (2) understanding how communities evolve and respond to disturbance (e.g., habitat loss and climate change), and (3) designing more efficient conservation and restoration plans. Two important concepts of an ecosystem are productivity (often measured by the total biomass) and biodiversity (often measured by species richness or the Shannon index that considers the relative abundance of species). The directionality of succession can potentially be indicated by the increase of net primary production. Per capita community productivity can be very high during the initial phases of succession, and decreases progressively as an upper limit to biomass is reached, and this phenomenon may be expressed as a sigmoid curve roughly akin to the logistic growth curve of a population. The upper limit of net primary production, or the maximum potential biomass, has been suggested to indicate the carrying capacity of biomass in a community (Monte-Luna et al., 2004).

If the number of species in a habitat is relatively low, immigration and diversification through disruptive selection will take place, which progresses until the region attains a maximum supportable load of species (Monte-Luna et al., 2004). This can also define the directionality of succession and, thus, the carrying capacity of biodiversity, depicting the maximum number of species or the 'biodiversity ceiling' that an environment can support. In fact, the form of species diversification on evolutionary timescales resembles the logistic population growth. By analogy, the number of species resembles the number of individuals or biomass, and the difference between rate of speciation and extinction the difference between fecundity and mortality (i.e., the intrinsic growth rate). The carrying capacity of biodiversity may be regulated by both physical factors such as climate and habitat heterogeneity and biotic interactions between species. Once the biodiversity reaches its ceiling, interspecific interactions can lead to competitive exclusion of some taxa, and adaptive niche partitioning (Monte-Luna et al., 2004). This can be further related to the r/K selection theory in ecology. It specifies a life-history tradeoff between the values of r and K that a species can possess. Species with high r and low K are opportunistic and often occur at the early stage of succession, whereas species with low r and high K are good competitors for limiting resources and often occur at the late stage of succession. An intermediate level of disturbance in a landscape, arguably, can create patches at different levels of succession, thus promoting the coexistence of these two types of species at the regional scale.

Human Carrying Capacity

Our planet is practically a closed system in terms of physical resources, and all human activity depends on these limited resources. Due to the continue growing of the world population and the rapid diminishing of pristine ecosystems from our exploration for consumption, the concept of carrying capacity is essential and should be considered paramount in our future planning. The Club of Rome has warned us the possible consequences of world population growth and industrialization for food production and resource exhaustion. They projected that within 50 years from now, the planet would reach its limit of growth (**Figure 3**), and thus advocated an urgent mutually beneficial integration of economics and ecology. Approaching carrying capacity means the deterioration of ecosystem services, the loss of biodiversity and habitat heterogeneity and the break down

Figure 3 World human population from 10 000 BC to AD 2050 when the carrying capacity of 10 billion is projected to be reached.

of ecosystem resilience (Arrow et al., 1995). This could lead to irreversible change, enlarged uncertainty to the biosphere, and even a regime shift of the world's living and climate systems. This concern has greatly influenced the popularity of environmentalism and the creation of the United Nations Environment Program.

Carrying capacity is commonly assumed to be constant in population dynamics models used for resource management. Human carrying capacity, however, is not a fixed, static, or a simple relationship, but is dynamic and adaptive. Humans can have more than one *K* value for a given resource at a given time, and the carrying capacity can vary markedly with culture and level of economic development (Daily and Enrlick, 1992). Earth's human carrying capacity cannot be characterized by a simple monotonic decline of the natural capital as the number of humans increase. For instance, Cohen (1995) studied a dynamic *K* model, with the change of carrying capacity affected by the population change rate.

Human carrying capacity describes the number of human beings that can be supported on a sustainable basis in a given area (or on the whole Earth) within natural resource limits and by human choices concerning social, cultural, and economic conditions (Franck et al., 2011). This concept is twofold: Biophysical carrying capacity is the maximum population that can be supported by the resources of planet Earth at a given level of technology, whereas social carrying capacity is the sustainable biophysical carrying capacity within a given social organization (Franck et al., 2011). In the case of very efficient agriculture the carrying capacity is only determined by the ratio of the total productive area and the nonagricultural used area (per person). For 2005 land cover, it can support 11.4 billion (10^9) (Franck et al., 2011), ranging from 7.7 to 12 billion in literature (Cohen, 1995). It has been predicted to be much higher than this range under certain scenarios, ranging from 30 to 100 billion (Franck et al., 2011). It is the limiting resource that constrains human carrying capacity. Although there exists the technology and economic willingness to develop intensive sustainable agriculture and other forms of food supply compatible with the aims of world development programs.

In a Malthusian framework, economic growth generates population growth; the population growth increases pressure on the natural resource base; the deterioration of the natural resource base decreases per capita food output; and the reduced per capita food limits population growth which, in turn, limits exploitation of the environment (Berck et al., 2012). This moderating feedback loop (density dependence) can be diverged by technological improvements. Population pressure on the resource base stimulates technological improvements in food production and hence facilitates continued population growth, which intensifies exploitation of the resource base (Berck et al., 2012). Alternatively, as income goes up there is increasing environmental degradation up to a point, after which environmental quality improves, causing an inverted-U shape (Arrow et al., 1995). Moreover, the detrimental impact from human society to ecosystems is often discounted over time and distance in decision-making, i.e., discounting future and faraway activities than can reduce carrying capacity. This encourages behavior that may reduce carrying capacity for future generations (Daily and Enrlick, 1992). Globalization further creates the illusion that all regions could simultaneously sustain populations that sum to more than global *K*, a typical Netherlands fallacy.

Biocapacity

Since the concept of sustainable development was put forward, it has become an ideal development mode and a common policy goal. To date, many indicators have been developed to assess the status of sustainable development, such as the life-cycle assessment, human development index by the United Nations Development Programme, barometer of sustainability, index of sustainable economic welfare, environmental pressure indicator, genuine progress indicator, sustainable technology development, environmental sustainability index, and ecological footprint (Rees, 1992). The latter has gained popularity due to its compatibility with the data format commonly derived from economic and social surveys. The ecological footprint for a particular population is defined as the total area of productive land and water ecosystems required to produce sufficient resources and assimilate wastes (Rees and Wackernagel, 1994). Biocapacity can be defined as the locally available carrying capacity of the ecosystem for generating resources and absorbing wastes (Rees and Wackernagel, 1994) and is constrained by the carbon sequestration rate of the ecosystem. According to the global average rate of carbon sequestration, we need to have about 17 ha of land and ocean area to absorb 1 metric ton of carbon emission. Ecological footprint and biocapacity, thus, represent the demand on and the supply from a regional ecosystem, respectively. As both ecological footprint and biocapacity are measured in the same unit (the global hectare: gha), it is straightforward to calculate regional ecological budget as surplus and deficit, after discounting the influence of trading. This specifies whether a regional population is potentially self-sufficient or is at least partially reliant on imported biocapacity. An ecological surplus has been proposed as a minimum criterion for sustainability.

Due to it being highly operable and easy to understand for public and policy makers, with the data required accessible from government yearbooks, to date they have been applied at a variety of spatial scales, from municipality/provincial level to national/global extents, covering all aspects of socioeconomic sectors, such as industry, education, agriculture, tourism, and waste management.

As a continuously developing field, the ecological footprint methodology has been widely criticized and amended. For instance, it has been considered a static indicator of weak sustainability as no dynamics and bounds are imposed on the level of ecosystem services and their demands. This has been partially solved by time series analysis and extrapolation (Yue et al., 2013). The introduction of spatial features, with the help of the geographic information system (GIS), has largely released the methodology from this constraint. To calculate the biocapacity of a region, one first needs to estimate the available areas of biologically productive land and water. Specifically, this biologically productive area can normally be divided into six or more main categories (cropland, grazing land, fishing land, forest, built-up area, and barren land), and the sizes of these six land covers can then be either extracted from government agencies or calculated using remote sensing images with the aid of GIS (Yue et al., 2013):

$$K = \sum_i A_i \cdot Y_i \cdot E_i$$

where A_i is the biologically productive area of land cover category i; γ_i is the yield factor of land category i and is calculated annually as the ratio of the local yield of a generic product to the global average yield of the same product. The yield factor converts local biologically productive land into units of global average productivity and thus facilitates comparisons across regions; E_i represents the equivalence factor of land cover category i and is a scaling factor needed for converting a specific land use type into a universal unit of biologically productive area (gha). Equivalence factor is calculated each year as the ratio of the global average productivity of a specific land type to the average productivity of all biologically productive land on the earth.

An important issue that is associated with area-based information is the scale dependency of spatial features. Evidently, the shape and size of different land covers are sensitive to the spatial scale as most landscape features are scale dependent and have self-similar, fractal structures. Put simply, results for biocapacity can be influenced by the resolution of the map (Yue et al., 2013). Since area-based information has been widely implemented for estimating the sizes of different land covers and therefore the biocapacity, it is important to at least be aware of the scale dependency of biocapacity and its impact on regional sustainability assessment (Figure 4). Moreover, there is often a power–law relationship between the biocapacity and population density (Figure 5), suggesting that biocapacity serves not only as a support for social development and human well-being but also sets an ecological limit for human activities (Yue et al., 2011). The biocapacity pressure index is the regional ecofootprint to biocapacity ratio and reflects the pressure posed by the human population on the local ecosystem. If the biocapacity pressure index is greater than one, the population is in ecological overshoot, indicating that regional development is not ecologically self-sustainable. If the biocapacity pressure index is less than one, the region is potentially self-sufficient (Yue et al., 2011).

Figure 5 The relationship between population density and biocapacity per hectare for 320 counties in Northwest China.

Relevance in Anthropocene

The growing number of studies on carrying capacity and its further development into different research fields have made this concept the most important issue in this century, for obvious reasons. First, the world has entered a rather peaceful era after the World War II, allowing both the living condition to proliferate and the economy to boom at a staggering pace. Although it took the modern human population of *Homo*

sapiens 200 000 years to reach its first billion in the early nineteenth century, the second billion took only another 100 years. Standing at 7 billion currently, the human population is projected to reach 10 billion in the middle of this century. The sheer number and the increasing per capita consumption rate in this era of Anthropocene place an enormous pressure on the planet's resource supply, both renewable and unrenewable. Humanity as a single species consumes more than one-fifth of the planet's net primary production each year. Will this great era of modern humanity continue to grow indefinitely; fluctuate around a sustainable level after a soft landing; or follow the boom–bust pattern of many earlier civilizations? The concept of carrying capacity has become a great reminder, a type of 'sword of Damocles,' hanging over humanity and driving it onto a sustainable path.

Second, as human population continues to expand, the planet's pristine ecosystems are degrading at a rapid rate due to man-made global environmental changes – climate change, habitat loss, biological invasion, soil erosion, and pollution, to name a few. Ongoing agricultural intensification, overfishing, industrialization, and urbanization further transfer how semi-natural ecosystems function and behave, creating many novel ecosystems that face high disturbance and gene flow. The planet's greatest asset – biodiversity, 100 million species strong – is quickly losing its grip. The rapid loss of species is estimated to be between 1000 and 10 000 times higher than the natural extinction rate, reaching 10 000 species extinction per year many of which disappear before they have even been formally described. Human society relies heavily on the health of ecosystem functions, the provision of ecosystem services and the benefit from biological diversity for cleaning air and water, stabilizing weather, maintaining soil fertility, dissipating waste, controlling pests, pollinating crops, generating power and discovering new antibodies, and providing food, timber, cloth, medicine, industrial material (coal, oil, gas, rubber, plastics, chemicals), together with minerals. We are not making anything new but utilizing products and services of the planet's ecosystem and physical system. To sustain humanity, we need to manage the planet's biosphere within its bearable margin to avoid disruptive regime shift and massive extinction, although some argue that we have already crossed the point of no return. On the positive side, the concept of carrying capacity is a powerful tool for assessing and conserving natural capital.

Cartographic Visualization

Menno-Jan Kraak, University of Twente, Enschede, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The cartographic visualization process, based on the statement "How do I say what to whom, and is it effective?" is explained for both presenting and exploring spatiotemporal data. The visualization environment and required functionality are described.

Setting

Assume that one is interested in an overview of the population distribution of a particular area. An option would be to give a written description such as: 'in the northeast only a few small towns are found, while in the southeast …' Before one gets a clear picture, several pages could have been filled, especially if a description of the relations of the towns with other geographic phenomena, such as the rivers or railroad network, is also incorporated. A better option is to tell this story using a map. Maps are the most efficient and effective means to transfer geospatial information. The map user can locate geographic objects, while the shape and color of signs and symbols representing the objects inform about their characteristics, such as the town's location and population size. Maps reveal geospatial relations and patterns and offer the user insight into, and an overview of, the distribution of particular phenomena, such as an area's population distribution.

The map easily allows one to answer questions of the nature 'Where …?' 'What …?' and 'When …?' These questions deal with the basic components of geospatial data: location, characteristics, and time, or their combination. The map discussed herein and found in Figure 1 will quickly result in answers to questions such as 'Where are the large towns located?' or 'What town has the highest number of inhabitants?' Questions regarding 'When?' depend on the map contents. Often the map is just a snapshot in time; for instance, the map in Figure 1 depicts the status as of 1998. In answering questions, another quality of maps will be revealed – the ability to offer an abstraction of reality. It simplifies by selection, but at the same time it puts, when well designed, the remaining information in a clear perspective. The map of the area only needs the boundaries of municipalities and a symbol for the number of people living in each town. In this particular case there is no need for roads, mountains, or other physical features. Maps like these are often static and come as they are, especially when they are printed on paper. On-screen maps often allow for interaction, such as getting data from the database behind the map.

Figure 1 Population distribution.

For more complex questions one needs more than just a static map. For instance, to study the impact of industrial development on the growth of towns, one would need the possibility to generate maps depending on the nature of the question. This could be to switch layers with information on or off. This would also include the possibility to view the data in alternative visualizations. Questions are no longer the simple 'Where?' 'What?' and 'When?' especially if, for instance, specific demographic models are included that can predict alternative future population trends based on census and socioeconomic data. These trends could be visualized in an animation. The mapping environment requires interaction and dynamics. This is what today's visualization is all about, as will become clear in the remainder of this article. However, according to the dictionary, visualization means 'to make visible.' From this perspective map making has always been visualization. Here the term visualization is used in the context that allows the map user to interact with the (digital on-screen) map (for a detailed discussion see Hearnshaw and Unwin, 1994; MacEachren and Taylor, 1994).

Visualization Process

Any map, static or dynamic, on screen or on paper, complex or simple, is created during what is called the cartographic visualization process. This process is considered to be the translation or conversion of geospatial data from a database into graphics. Predominantly these are maplike products as is schematically explained in Figure 2. This process should be seen in the context of geospatial data handling, which is the acquisition, storage, manipulation, visualization, and use of geospatial data in the context of particular applications.

Figure 2 The cartographic visualization process.

During the visualization process, cartographic methods and techniques are applied. These can be considered as a kind of grammar that allows for the optimal design, production, and use of maps, depending on the application. The process is guided by the phrase 'How do I say what to whom, and is it effective?' The phrase holds four key words: *How* refers to cartographic methods and techniques (in the case of **Figure 1** a proportional point symbol map has been chosen); *What* refers to the geospatial data (**Figure 1** deals with quantitative population data); *Whom* refers to the map audience and the purpose of the map – (the map in **Figure 1** is rather basic and could function in a newspaper or school atlas); and *Effective* reflects the usefulness of the map (do the map readers understand the message the map intends to bring, an overview of the area's population distribution).

The producer of maps could be a professional cartographer, but could also be an expert who is mapping, for instance, vegetation stands using remote sensing images or health statistics in the slums of a city. With today's availability of Web mapping tools, the mapmaker could be anyone – with or without any notion of cartographic design.

The visualization process can vary greatly depending on where the visualization takes place and the purpose for which it is needed. Visualizations can be, and are, created during any phase of the geospatial data-handling process. They can be simple or complex, while the production time can be short or long. Some examples are the creation of a full, traditional topographic map sheet, a newspaper map, a sketch map showing a route, a map from an electronic atlas, an animation showing the growth of a city, a three-dimensional (3D) view of a building or a mountain, or a real-time display of traffic conditions on a mobile device. Other examples include 'quick and dirty' views of part of the database, the map used during the updating process, or during a geospatial analysis. The environment in which the visualization process is executed can vary considerably. It can be done on paper, on a stand-alone personal computer, or on a networked tablet computer.

Many tools are available to visualize the data. These tools consist of functions, rules, and habits. Algorithms to classify the data or smooth a coastline are samples of functions. Rules tell us, for instance, to use proportional symbols to display quantities or position an artificial light source in the northwest to create shaded relief maps. Habits, or conventions as some would call them, tell us to color the sea in blue, lowlands in green, and mountains in brown (Robinson et al., 1995; Kraak and Ormeling, 2011).

Visualization and Cartography

In the past, even dealing with incomplete and uncertain data, the visualization process nearly always resulted in an authoritative map. The maps created by a cartographer were good enough for the user. This shows that cartography, for a long time, has been very much driven by supply rather than demand. Somehow, this is still the case. However, nowadays, it is also accepted that just making a map is not the only purpose of cartography. Especially since 1980, many people have become involved in making maps. The widespread use of Geographical Information Systems (GIS) has significantly increased the number of maps being created (Longley et al., 2010). Even the spreadsheets used by most office workers today have mapping capabilities, although many people are probably not aware of this. The opportunities offered by the World Wide Web lead to an incredible increase in maps produced. Some websites, such as Google Maps, Bing Maps, or Open Street Map produce over a million maps a day! Many of these maps are not produced as final products, but rather as intermediate products to support the user in his or her work dealing with geospatial data. The map, as such, has started to play a completely new role: it is not just a communication tool but also a tool to aid the user's (visual) thinking process.

This process is being accelerated by the opportunities offered by hardware and software developments. These have changed the scientific and societal needs for geo-referenced data and, as such, for maps. New media not only allow for dynamic presentation but also for user interaction. Users do expect immediate and real-time access to the data, and geospatial data has become abundant. In what is known as a Web2.0 environment, people collect and map their own location-based and annotated data. They do so using mobile phones and make their maps available via social media such as Facebook or Twitter. These massive amounts of data can also be mined for other purposes.

These developments have given the word *visualization* enhanced meaning since progress in other disciplines has linked the word to more specific ways in which modern computer technology can facilitate the process of 'making visible' in real time. Specific software toolboxes have been developed, whose functionality is based on two key words: *interaction* and *dynamics*. Separate disciplines called *scientific visualization* (McCormick et al., 1987) and *information visualization* (Ware, 2012) have developed and have had a major impact on cartography. If applied in cartography, dynamic interaction offers the user the possibility of instantaneously changing the appearance of the map. Interacting with the map will stimulate the user's thinking and add a new function to the map. As well as communication, it will prompt thinking and decision making.

These developments have stimulated a model for map-based visualization (DiBiase, 1990). As such, it is also known as 'geovisualization' (MacEachren, 1995; Dykes et al., 2005), which covers both the communication and thinking functions of the map. Communication is described as 'public visual communication' since it concerns maps aimed at a wide audience. Thinking is defined as 'private visual thinking' because it is often an individual playing with the geospatial

data to determine its significance (see Figure 3). On a lower level, different visualization stages can be recognized; each stage requires a different strategy from the perspective of map use, based on audience, data relations, and the need for interaction. These stages are exploration, analysis, synthesis, and presentation.

From Figure 3 it is obvious that presentation fits into the traditional realm of cartography, where the cartographer works on known geospatial data and creates communicative maps. These maps are often created for multiple uses. However, exploration often involves a discipline expert creating maps while dealing with unknown data. These maps are generally single purpose and are related to the expert's attempt to solve a problem. While dealing with the data, the expert should be able to rely on cartographic expertise provided by the software or some other means.

This process describes the 'democratization of cartography' (Morrison, 1997). Morrison explains that 'using electronic technology [means that] no longer does the map user depend on what the cartographer decides to put on a map. Today the user is the cartographer'. And 'users are now able to produce analyses and visualizations at will to any accuracy standard that satisfies them (Morrison, 1997).'

Visualization and Exploration

What is exploratory cartography? The environment has just been described: a person is trying to solve a particular geoproblem and is exploring various geospatial databases. Exploration also means working with unknown data. However, what is unknown for one is not necessarily unknown to others. For instance, browsing Google Earth is an exploration for most of us because of its wealth of information. With products like these, such exploration takes place within boundaries set by the producers. Cartographic knowledge is incorporated in program wizards resulting in predesigned maps. Some users feel this to be a constraint, but those same users will no longer feel constrained as soon as they follow the Web links attached. This example shows that the environment, the data, and the type of users influence one's view of what exploration entails.

Returning to the sentence driving the visualization process, 'How do I say what to whom and is it effective?' – some similarities as well as differences exist between modes of visualization that entail presentation and those that involve exploration. 'How?' still represents the cartographic methods and techniques. However, new technology is emerging that offers challenges and opportunities, such as animation, the application of the third dimension and virtual reality, multimedia, and so forth. 'I' is no longer just the cartographer, but an expert geoscientist. In the very near future, it can probably be just anyone having access to the World Wide Web. 'What?' no longer represents a relatively well-defined and known data set – at least, certainly not from the user's perspective. 'To whom' seems to be simpler than before; it is not a relatively well-defined user group but the same person represented by 'I,' the expert geoscientist in the role of cartographer. 'Effective' raises some interesting questions. When a map is used, the information to be transferred is known and, for all problems involved, can somehow be measured. But how can the visual thinking process be measured? If it is considered positively, is it because of the efficient graphics or because of the geoscientist's clever thinking? These questions become more complex if we realize that we do not even know the initial aim of the visualization in these circumstances.

The most prominent change is the shift from supply-driven cartography to a demand-driven approach. Although having many people making maps without any cartographic knowledge might seem wrong, those noncartographers will also introduce fresh views, for instance as described by Keller and Keller (1993). They distinguish three steps in the visualization process: the first identifies the visualization goal; the second removes mental roadblocks; and the third designs the display in detail. In the second step, Keller and Keller suggest taking some distance from the discipline in order to reduce the effects of traditional constraints. Why not choose an alternative mapping method? For instance, show a video of the landscape next to a topographic map. New, fresh, creative graphics could

Figure 3 The visualization process: visual thinking and visual communication.

be the result; such graphics might also offer different insights and would probably have more impact than traditional mapping methods. During the third step, which is especially applicable in an exploratory environment, one has to decide between mapping data and visualizing phenomena.

An exploratory visualization environment offers the tools to act in the ways previously suggested. Such an environment should allow the user to look at geospatial and other geo-referenced data in any combination, at any scale, with the aim of seeing or finding geospatial patterns (which may be hidden). Geospatial patterns can be defined as variations in location, attributes or time, or a combination of any of the three geospatial components within an area of interest. One of the first concepts of visual geospatial data exploration was introduced by Monmonier (1989) when he described the term *brushing* (see Figure 4). This is when the selection of an object in a map automatically highlights the corresponding elements in the other graphics. Depending on the view in which one selects the objects, there is geographical brushing (clicking in the map), attribute brushing (clicking in the diagram or table), and temporal brushing (clicking on the time line). As such, the user gets an overview of the relation among geographic objects based on location, characteristics, and time.

Visualization Functions

What are the basic requirements of an exploratory visualization environment? The necessary functions described in the following sections need high interactivity options.

Basic Display

Map displays need tools to allow the user to pan, zoom, scale, transform, and rotate the image contents. These geometric tools should be available and independent of the dimensionality of the displayed geospatial data. Figure 5(a) illustrates panning and zooming facilities. Another option could be rotating the map. This last function is of particular need when displaying 3D maps, since it also allows objects that otherwise might be hidden by other objects to be seen.

Figure 4 Brushing.

Navigation and Orientation

This involves the keys to the map. At any time, the user should be able to know where the view is located and what the symbols mean. To illustrate this function, Figure 5(b) shows a map with its marginal information as well as the coordinates at the cursor location in the map.

Query Data

During any phase of the visualization process, the user should have access to the geospatial database to query the data. The questions should not necessarily be limited to a simple 'What?' 'Where?' or 'When?' As Figure 5(c) shows, clicking a geographic object in the map reveals the information available in the database, as well as the hyperlinks that are attached to the object.

Multi-Scale

Combining different data sets is a common operation in an exploratory environment. The chance that these sets will have the same data density or the same level of abstraction is unlikely. Generalization operators to solve these multi-scale problems remain necessary, if not just to make sure zoom-in and zoom-out operators result in sensible maps. In Figure 5(d) zooming-in results in a more detailed map.

Reexpression

To stimulate visual thinking, an unorthodox approach to visualization was recommended. This requires options to manipulate data behind the map or offer different mapping methods for displaying the data. An example of data manipulation is the application of several classification systems, while the use of different advanced map types to view the same data represents display differences. Figure 5(e) illustrates how the population data shown in the figure's main map can be displayed alternatively. The upper inset shows a prism map (a 3D representation of the data in which the height of the area corresponds to the attribute value; the big towns have high columns) and a cartogram (a map in which the area of a geographic unit is equal to the attribute value and not, as usually, to its geographic area; the highly populated towns take a lot of map space).

Multiple Dynamically Linked Views

These tools represent a combination of multimedia and the brushing technique already mentioned. The user will be able to view and interact with the data in different windows, all representing related aspects of the data. These views do not necessarily contain maps; video, sound, text, and so forth can all be included. Clicking an object in a particular view will

Figure 5 Exploratory cartographic functions: (a) basic display; (b) navigation and orientation; (c) query; (d) multi-scale; and (e) reexpression.

show its geospatial relations to other objects or representations in all the other views (see Figure 6).

Animation

Maps often represent complex processes that can be well expressed by animation. Animation can be used for temporal as well as nontemporal changes in geospatial data. Aspects to be solved are related to the interface (user interaction – navigation) and the legend. Since the exploratory user will also be the creator of the animation, he or she should be able to influence the flow of the animation.

Visualization Environments

Most cartographic components of geographical information systems can only handle one or two of the functions described in the previous section. Scientific and information visualization software might have the most functions available, but it lacks the typical geo-referencing options needed to deal with geospatial data, options that are found in the typical Geographic Information Systems software. However, operational experimental exploratory visualization environments do exist in academic environments. An example of an early experimental environment is the Cartographic Data Visualizer (CDV) (Dykes, 1997). The program requires a base map (administrative boundaries) and statistical data. From the menu on the left the user can select active variables and visualizations. Options are choropleth (or polygon) maps, proportional circle maps, cartograms, and noncartographic visualization such as dotplots and scatter diagrams. When creating these different views on the data, they will all be linked together. Clicking an area in a map or a symbol in a diagram will highlight the corresponding area/symbol in the other views. The user has several options available to choose the layout of each of the views. One can also execute basic calculations to create new variables or classify the data according to different methods. CDV is, by the nature of its functionality, capable of showing geospatial patterns that would not be apparent when single maps or diagrams are viewed.

Conclusions

Packages with the functionality similar to CDV offer an advanced cartographic visualization environment. However, remembering 'How do I say what to whom, and is it effective?' leaves the question open if it indeed works. From a technical point of view it certainly does, but can the user handle all those linked views? It is argued that if users can change their perspective on the data through selection and transformation, as well as alternative visualizations, meaningful relations among data variables are more likely to be revealed. For some

Figure 6 A typical view of a CDV session.

products, usability is easy to determine; for others it is quite a job. To understand how maps work is not easy (Wood and Fels, 1992), especially as we change into a demand-driven mapping environment. In the supply-driven environment, it was known what the map should tell and who the customers were. Today cartographers deal partly with providing facilitating tools to visualize geospatial data. How the tools are used remains, for the moment at least, unknown. These trends will only increase as more and more maps are produced via the World Wide Web by both cartographers and mapmakers. One has to find out why someone wants to make a map in order to be able to judge the future tools that need to be developed.

Abstract

Cartography is "the discipline dealing with the conception, production, dissemination and study of maps" (International Cartographic Association, 1996). This article covers the basic concepts of cartography as well as the role of maps in society.

Introduction

Cartography is "the discipline dealing with the conception, production, dissemination and study of maps" (International Cartographic Association, 1996). It is one of several mapping sciences, including geodesy, surveying, aerial photogrammetry, and satellite remote sensing. It is closely allied with geographic information systems, geographic information science, and geomatics; the term cartography now coexists with many other terms that have developed as modern electronics have come into use in the production, dissemination, and study of maps. Responding to changing social, intellectual, and technological innovations, cartography has risen from its roots in gestures and marks on the ground to a highly sophisticated and varied endeavor that uses data from aerial photographs, satellite images, global positioning systems, crowd sourcing, and the harvesting of social media. Traditional concepts in cartography, including scale, projection, spatial relationship, generalization, and symbolization and data modeling, remain central. Critiques of cartography have presented views about how maps function beyond their role as scientific documents, focusing attention on the underlying culture and motivations for mapping and their socially constructed nature (Harley, 1989). In the last half of the twentieth century, the concept of maps as communication devices brought the user to the center of concern for the mapmaker (MacEachren, 1995). That development distinguished the period from a tradition more limited to a focus on visual representation, i.e., the logical encoding of data.

Traditionally, maps have been classified as general reference (showing a variety of individual features), thematic (showing a distribution), or somewhere between these ends of the spectrum. Even though the classification is inexact and the explosion of mapmaking using new tools and data sources has further taxed the system, the terms are still used. They are often used now to distinguish different features on a map: A population map has thematic data (population), but it probably also has reference data such as political boundaries.

Cartography as an academic discipline has most often been found in geography departments in colleges and universities in the United States and Canada. It has commonly been an independent department in Europe and other parts of the world. Labels for some of those departments have changed in recent decades. Commercial enterprises, nonprofit entities, and government agencies that produce maps generally have large cartography departments that are central to their operations, though they, too, may bear some other label.

The term 'research' within the field of cartography has at least two distinct meanings. One is the systematic gathering of information from a variety of sources for compilation into a coherent map. The other is the quest for discovery of knowledge about maps, the processes associated with them, and the underlying meaning of maps within the culture in which they exist. The former definition is closely associated with government and commercial map production and the latter with academic cartography. The subject matter of academic cartographic research ranges from historical studies of the cultural, technical, and political context of maps to the changing processes of production to the ways in which maps are used in wayfinding and in the production of knowledge.

The relationship between people and maps, including symbol perception, the development of map-reading abilities, and cognitive processes in map use, was of special interest in cartography in the late twentieth century, as were the processes by which maps could be produced by computer. Maps delivered electronically and on demand have had a profound effect on how maps are obtained and used, and modern tools have made possible a wide range of innovative and dynamic products. The common paper street and road maps of previous decades, for example, have largely given way to maps on the screens of computers, global positioning system devices, and smartphones. The choice of scale for these displays affects what and how features are symbolized (and vice versa) and the ability to see less information at a time, but far more information as the user scrolls seamlessly over space. Users can also choose which features to display (e.g., restaurants, parks, or hotels) and whether to turn on voice directions when driving or walking or otherwise navigating from place to place.

Although maps are most closely associated with geography, practitioners in many disciplines and professions use the map as a device for recording and preserving information, as a tool in research, and as pedagogical illustration. Given the use of computers in mapping, their production is no longer strictly the domain of professional cartographers, or even others in the mapping sciences, as it once was. Anyone with a computer and appropriate software can produce maps, albeit not always the ones they would like to see because data may not be available or the mapping software with which the person is familiar may not produce the desired product. This democratizing of mapping has had both negative and positive effects. The products of nonspecialists range from misleading to highly insightful and creative. On the other hand, some types of maps are now far more widespread and are available in a more timely

way to fit immediate needs than in the past, and they are becoming less constrained by convention. Even more important, highly motivated mapmakers from many disciplines and often with high levels of technical expertise are producing maps that are truly innovative (e.g., Weldon Cooper Center for Public Service, 2013).

Cartography and its products have a profound effect on human thinking and behavior. The map is a metaphor for the real world and is often the model that shapes it. Existing hills and valleys, rivers, and political boundaries are recorded on maps, but decisions about surface excavation, river redirection, or political redefinitions are marked on maps and become reality. The terms 'map' and 'mapping' have become common metaphors in everyday language; 'on the map' signifies importance, and 'mapping a strategy' implies attentiveness, organization, and purpose in the planning of actions.

Cartography has responded to changing social, intellectual, and technological conditions throughout history, and the permeation of computers into all aspects of life in the late twentieth century brought on profound changes that go well beyond who can make a map. Cartography transformed from a data-poor to a data-rich field, as information is now gathered with aerial and satellite imaging, global positioning systems, and computerized field systems. In just 11 days in February 2000, the Shuttle Radar Topography Mission collected high-resolution elevation data for nearly the entire globe (Jet Propulsion Laboratory, 2009). Inexpensive computer storage and the Internet have made it possible to share and receive massive amounts of data. Professional cartographers are now heavily involved in information management and in creating mechanisms for shared use of data. Scientific visualization in cartography, which implies the use of maps for discovery of knowledge and generally involves user interaction with the map, has gained considerable attention in recent years as a result of the ubiquity of computer usage in spatial representation.

Major Cartographic Concepts

Mapping the Earth's surface involves the concepts of scale, resolution, projection, spatial relationships, generalization, symbolization and data modeling, and categories of maps. Some level of understanding of each of these concepts is inherent in every instance of the employment of a map.

Scale

The map is a scaled model of the Earth's surface (or of the surface of some other planetary body), and the reduced size is one of its most useful features. The Earth itself is too large for ready comprehension.

There are three types of scale expression commonly used on conventional maps: verbal, representative fraction, and graphic (**Figure 1**) (Robinson et al., 1995). Although each can refer to either distance (linear scale) or area (areal scale), linear scale is by far the more commonly used. Areal scale is generally indicated only if area is consistently scaled over the entire map. Since distance cannot be consistently scaled, no such constraint is associated with the appearance of a linear scale indicator.

Figure 1 The three types of scale expression, illustrated in both linear and the rarely used areal form. (RF = representative fraction.)

The terms large and small, or the comparative terms larger and smaller, are often used in connection with scale. Larger scale refers to a map that is a larger representation than a smaller-scale map of the same area. A map at 1:100 000 of a given area is larger than a map at 1:200 000, and, accordingly, 1:100 000 is a larger scale than 1:200 000.

Explicit scale expression is not the only indication of scale on maps (Eastman, 1981; Brewer, 1990). Map content and design give scale clues as well. Double-line streets, for example, immediately convey that the map is large for the size of area represented and is therefore a relatively large-scale map; a shaded relief background and sparse line work almost always indicate that the map is small relative to the area represented and is therefore a relatively small-scale map. Scale clues are becoming increasingly important because the user of an animated map often cannot use an explicit expression of scale while observing the changing map. Because users seldom measure distances or areas on thematic maps, especially those of familiar areas displayed on the Web, it is becoming increasingly common to omit scale expressions on them.

Resolution

Resolution is related to scale. For images captured electronically (say, by satellite) and for maps displayed electronically, resolution is the distance on the Earth's surface that is covered by each pixel. It is an indication of how much detail has been captured and how much detail can be represented in a visual image made from the data. For example, a satellite image with a resolution measured in kilometers cannot capture individual buildings, whereas another image with a resolution measured in centimeters could capture not only buildings but much smaller features. The resolution of the image does not dictate the scale of display, although an image with coarse resolution will not usefully be displayed at large scale and the image with fine resolution is inefficient for small-scale display. If many kilometers are represented by each pixel, the map could not show sufficient detail to navigate in a city, whereas another with a resolution in centimeters would likely contain too much detail for that purpose. Detail on maps, however, is also a function of design choice, whether by the mapmaker or the user. A map of population by county is of much finer data resolution than one showing the data by state, even if the two maps are shown at exactly the same display scale. A map showing only major roads and their names might also be capable of showing more minor roads, or additional

information of some other kind, if the person using the map display chooses to turn on the additional features. There is a lower limit scale at which data at a given resolution can be represented, and there is an upper limit scale at which the map is noticeably wasteful of space and inefficient for conveying information (Tobler, 1988).

Projection

The term 'projection' refers to the system by which points on a spherical or spheroidal surface are assigned to points on a flat surface. Every point on the sphere or spheroid has a corresponding point on the flat map. Perhaps the most fundamental observation about map projections is that linear scale cannot be the same everywhere. In other words, map projections are geometrically distorted representations in contrast to globes, which maintain a shape very close to that of the planet and a scale that is virtually the same everywhere. There are many map projections in use and the five represented in **Figure 2** illustrate a variety of shapes and relative sizes of landmasses that can result when different systems of projection are applied.

Although it is necessary to tolerate distortion when projecting the Earth onto a flat surface, the distortion in map projections is systematic and in some cases highly useful. Every rectangular projection of the world, for example, has one or two straight lines on which there is no distortion, and distortion increases at right angles away from the line(s) of no distortion. Although small-scale maps of large areas have major visible distortion, maps of small areas, say a city or small region, have so little distortion when the projection is centered on the represented area that the distortion is of interest only for the most exacting uses.

Figure 2 Five map projections showing a variety of shapes and sizes of landmasses when different projection systems are applied: (a) orthographic, the projection that looks like a view of a globe; (b) gnomonic, a very distorted projection, but the only one on which all great circles are straight; (c) cylindrical equal area, which preserves correct sizes of all areas but has extreme changes in linear scale; (d) Alber's, which is equal area and is commonly used for the USA; and (e) plane chart, which represents all degrees of latitude and longitude at the same length regardless of their length on the Earth's surface.

The development of geographic information systems resulted in renewed interest in map projections in the later decades of the last century because many maps were transformed into digital files and data had to be 'unprojected' (transformed from flat map Cartesian coordinates to longitude and latitude) or 'reprojected' (transformed to another projection) to be compatible with data from other maps or other sources. Data are now generally gathered directly in digital form, but because coordinate systems (e.g., Universal Transverse Mercator) by which data are gathered are tied to specific map projections, the user of the data must be keenly aware of that underlying projection. Even the limited amounts by which map projections affect location within small areas will affect the compatibility of the multiple data sets that are brought together to produce a map. Digital files are also commonly tied to a world projection, not one centered on the user's particular small area of interest. If the underlying world projection is one on which each degree of latitude and longitude is plotted at the same length, even a small patch of land such as a property parcel can be greatly distorted. The projection used for a small-area map is of little concern only when the projection is centered on that small area.

Despite the impossibility of maintaining consistent linear scale on a map projection, there are two other properties that may be maintained, though not both on the same projection. When, at every point on the map, maximum linear scale distortion is compensated by opposite distortion in the opposite direction, area scale is maintained. On the other hand, if the linear scale is the same in every direction at each point, angles at all points will be maintained (not angles between distant points, but angles right at the individual points). The terms for these two categories of projection are equal area (or equivalent) and conformal (or orthomorphic), respectively. Many projections have neither compensating nor equal linear scale in opposite directions at all points; these projections are neither equal area nor conformal.

Some projections have special properties that make them useful for specific purposes. The Mercator projection, when centered on the equator, shows all loxodromes (or rhumb lines, i.e., lines of constant geographic direction) as straight lines. This property has been important to navigators. It was a profound development because most loxodromes on the Earth (and on globes) are spirals and the Mercator projection simplified route planning. The projection suffers from extreme deformation of area, and, like many other projections, has been used inappropriately (Monmonier, 2004). The Mercator maps hanging on classroom walls have led many students to think of South America and Africa as a relatively small land bodies relative to the greatly exaggerated high-latitude landmasses of Greenland and Russia, whereas South America is over eight times the size of Greenland and Africa is about 1.75 times the size of Russia.

There are more than 100 named projections (see Snyder, 1993), and cartographers try to choose a projection (named or not) that is appropriate for the mapping purpose at hand. The discrete naming of projections, while providing convenient reference, obscures the fact that there are an infinite number of ways to represent the Earth on a flat surface. Computer construction of projections is resulting in increasingly tailored projections (Laskowski, 1997).

Spatial Relationships

Maps show spatial relationships in a readily comprehended form. Metric relationships include distance, direction (angle), and area; topological relationships include such properties as connected to, inside, outside, left of, and right of. The concept of spatial relationship also includes spatial (or geometric) form; an entity may be considered to have a footprint of a point, line, or area, and if quantities are associated, the entity may be thought of as a pole, ribbon, or volume. Spatial form also includes shape (e.g., Long Island vs Martha's Vineyard) and distribution ('more of something here than there'). The relevant spatial relationships vary with the type of map and with how it is used. Street map users want to know the location of a feature to which they are navigating and the turns and distances to reach it. Users of a world population map want to know where population is concentrated and where it is sparse.

Like the general concept of scale, spatial relationship is often taken for granted by the practiced map user. Sometimes the reason for using a map is not the spatial relationship itself, but what it means. A 'hot spot' on a map showing cancer rates suggests the need for further study and possible action; the spatial relation on the map is simply the trigger and is suggestive, at best, of any factors of causation. Whether a street, population, or cancer map, it is the spatial relationships that make it a useful device. Without them, there would be no need for a map.

Generalization

As scaled representations of the Earth or of portions thereof, every map is generalized. Lines have fewer details in them than present in the feature on the Earth's surface, and only selected features are shown. When quantities are depicted, they are usually shown by category rather than by exact value. Generalization is highly useful in focusing the map on important information instead of cluttering it with overabundant detail. It also means that some important features may not be there, not because they do not exist but because they have been generalized out of the map.

Despite the obvious necessity for generalization in making representations that are literally thousands and millions of times smaller than the original territory, it is not always understood. The small street maps of major cities that appear on paper road maps may be assumed by users to include every street, and a surface feature that falls between the contours of an elevation map may surprise and confuse the hiker. The failure of a map due to generalization is one of the reasons that there are many different maps of the same area at different scales and with different selections of features. The larger the scale (i.e., the larger the representation of a given area), the less generalization is necessary and the more useful it is likely to be for finding small features. The smaller the scale (the smaller the representation of a given area), the more likely it is that broad patterns will be visible because of the lack of obfuscating detail.

The relationship between scale and generalization is not an exact one. Some maps have much more detail than others of the same physical scale. The capacity of a map for depicting detail and the clarity of a detailed map for the user are affected by design choices. A traffic map, for example, with color of road segment indicating vehicle density is a clearer representation than one using road width, which is likely to have overlapping symbols or considerably fewer categories.

Symbolization and Data Modeling

The very act of representing a feature with a symbol is a form of generalization. The symbol is not the original and every map is a set of symbols. Mapmakers have been highly creative in employing symbols.

Geometrically, mapmakers can employ only points, lines, and areas as symbols on flat maps, though they may be used so as to simulate the illusion of a third dimension. The use of three-dimensional media, such as molded plastic or the product of a 3D printer, allows the explicit use of volume as a symbol. Dynamic mapping can include an additional dimension, usually time or changing point of view. The development of virtual reality allows the illusion not only of a third dimension, but of the intersection of surfaces and of movement through perceived three-dimensional space or over a period of time. Regardless of medium, the geometry of symbols generally reflects the way in which humans think of the object relative to the scale of the map. For example, a city is a large area on a street map but a point on a world map. A river on a local, large-scale engineering map is an area, but the same river appears as a line on a smaller-scale regional map. On thematic maps, on the other hand, symbols often represent conceptual volume, not specific features. A dot map of population, for example, uses numerosity of dots to represent quantities of persons.

There are a limited number of characteristics of symbols, called 'visual variables,' which can be used to represent the characteristics of the feature represented (Bertin, 1983). Darkness–lightness of the symbol and size are the most commonly used characteristics to represent quantity. Shape, color hue, and orientation most often represent differences in kind. Patterning in area symbols may also be used to distinguish characteristics of features.

The modeling of geographic space in digital files introduces a different form of representation from that on paper or similar physical medium (Peuquet, 1991). Geometric concepts of point, line, area, and volume are still valid, but there is no scaled physical representation or visual symbols associated with features. Rather, numbers represent location, and codes or descriptive terms represent what exists at a location. These digital files can be thought of as data models as opposed to a physical model. They can almost always be converted into a map, but they are much more flexible. A digital elevation model, for example, i.e., a file of elevation values at points, can be converted into any of the maps in **Figure 3** and is often portrayed with a combination of these techniques.

Figure 3 Four ways of representing a set of elevation data; lines are used in the contour map (a) and three-dimensional diagram (d), whereas area symbols are used in the layer-shaded map (b) and in the shaded relief map (c).

Categories of Maps

In the latter half of the twentieth century, maps were often broadly categorized as general reference or thematic. Although the distinction is highly artificial, often difficult to apply, and increasingly controversial, it is still in use. A general reference map (Figure 4) shows a variety of individual features, such as cities, rivers, regions, lakes, and oceans, and is generally used to find specific features. The general reference map is selective of features in any category: only 'important' cities, rivers, etc., are identified. Although lettering on the map often stands out visually, there is limited visual hierarchy among the features of the map, as all the features must be distinguishable from one another. A thematic map (Figure 5) shows a distribution of one or more phenomena and is used to visualize spatial form. The thematic map is generally based on all the known instances of the phenomenon even though none is shown individually. The thematic map generally has clear visual hierarchy, with the symbols representing the featured distribution (e.g., the colorful symbols representing mussels in Figure 5) standing out more than other features on the map (e.g., lines representing state boundaries).

Sometimes a third category, such as navigation maps, is added. Others consider the general reference and thematic categories to be opposite ends of a scale, with individual maps fitting somewhere between. Navigation maps, such as street guides, are then placed near the general reference end because many different specific items are represented, but not necessarily every item in a category. They have certain thematic qualities, however, because of the focus on the features relevant to finding one's way. Inventory maps, such as a map showing the residence of every patient with a certain disease, are closer to the thematic end of the scale, but they share the general reference characteristic in that individual items are shown.

There is good argument that the general reference–thematic classification refers more to map use than to maps themselves. One can look at a thematic map to see how large one political unit is relative to another, which is a function generally associated with the term 'general reference.' Likewise, one can look at a general reference map and observe overall pattern of drainage or evidence of population, uses generally associated with the term 'thematic' (Robinson and Petchenik, 1976).

There are valid arguments as well that these categories are so artificial that they are not useful (Wood et al., 2010). There is no question that many, if not most, maps are difficult to place into these categories, especially with the flexibility afforded by data availability and production possibilities of electronic mapping. A recent textbook avoids any use of such categorization (Krygier and Wood, 2011).

Design

The design of a map is the whole set of decisions on how underlying information is symbolized, and it also refers to the resulting look of the map. It has been affected by virtually every technological development in the history of mapping, and the ability of the observer to distinguish differences between maps printed using intaglio as opposed to lithograph exemplifies the profound influence that technological change has on the way a map looks. In the late twentieth century and early twenty-first century, electronic production and dissemination are having profound influences on design. Traditional rules of thumb, such as 'the darker the more,' when depicting quantitative information on the traditional monocolor paper map have given way to rules of thumb about using the full range of color characteristics effectively. In digital display, using a bright color on a dark background may be far more effective for emphasizing a high category of quantitative data than dark on a light background. We can also use motion for emphasis; a blinking item on the map will surely catch attention. Even more important, maps need not be made for everyone but can change to meet user needs. Color choices, for example, can accommodate users with red-green color deficiencies, but the rare person with a yellow-blue deficiency need not be left out. An alternate version of the map, identical in all respects except the choice of colors, can be an option.

Figure 4 Madagascar physiography, an example of a general reference map, Central Intelligence Agency, 2014. https://www.cia.gov (original is in color).

Tools are also available on the World Wide Web to assist in design decisions. ColorBrewer helps a map author to find combinations of colors that will be effective for various media and determine which combinations are suitable for those with red-green deficiencies (Brewer et al., n.d.). TypeBrewer gives assistance in the selection of type (Sheesley, 2006).

Most maps today are viewed on electronic devices, not in books or printed paper sheets. A new set of maps on the Web, if

Figure 5 Zebra and quagga mussels map, an example of a thematic map, US Geological Survey. http://nas.er.usgs.gov/taxgroup/mollusks/zebramussel/ (original is in color).

content or design is sufficiently attractive, can draw thousands of views within a short time of posting because the link is shared on social media. Having been created by a wide variety of authors, online displays are broadening the way in which maps are designed, with a mixture of quality in the results. Some of the old common design features, such as a neat line (line delineating the area of the map display), are used far less because they are less often relevant. On the other hand, there is little doubt that some maps are designed better than others and that some of the traditional as well as new design guidelines are useful.

Technology is not the only influence on design. Intellectual changes are reflected in map textbooks (Krygier and Wood, 2011), graphic critiques more broadly (Tufte, 2001), and publications of exemplars in cartography (Wallace and Huffman, 2012).

The History of Maps and Cartography

The history of cartography begins earlier than recorded time and in all likelihood had its origins in gestures and ephemeral marks in the soil (Godlewska, 1997). Maps have undergone profound development in the millenia since then, and the following summary is based on Thrower's (1996) readable account.

The development of civilizations and of cartographic practice were probably highly intertwined, and at least some cartographic artifacts remain from ancient Mesopotamia and Egypt, including a clay tablet from roughly 3800 BC with mountains and a river. Extant land ownership maps date to 2000 BC. The development of grid systems, associated with less subjective and more scientific approaches to mapping, was reflected in written materials in China in third century AD, and the earlier development of paper in China provided a flexible and highly portable physical medium for drawing maps.

The concept of the world as a sphere was basic to the development of logical representation of large areas of the world. Measurements make sense only when the curvature of the planet is taken into account. The idea seems to have had its origins with the Pythagoreans and was supported in work by Plato and Aristotle. Eratosthenes (276–196 BC), who served as the librarian at Alexandria, used the concept of the spherical

Earth and the relationship between noon Sun angles at different locations to measure the size of the planet. Because the exact length of a stade, the unit of measure in use at the time, is not known, it is difficult to know exactly how accurate his estimate was, but it seems to have been remarkably close and a better estimate than several that followed, as scholars attempted to correct the figure. A successor in his position in the second century AD, Claudius Ptolemy, compiled the seminal tome entitled *Geographia* that contained a guide to making maps, including instructions for several map projections and the latitude–longitude location of about 8000 places.

Mapmaking in China and South Asia is characterized by remarkable developments in roughly the same time period as the accomplishments of the ancient Greeks. There is reference to a map on silk in the third century BC, and maps were used by the military and administrators in the Han Dynasty. In later centuries, the first printed map appeared in China well before the development of printing in the West (approximately 1153 AD vs 1472 AD).

European cartography during the Middle Ages was characterized by maps that are highly schematic by modern standards but were important cultural documents of their time, having been associated with religious institutions and beliefs. One schema was a circular map with east at the top showing Asia as the upper section of the circle, separated from Europe in the lower left and Africa in the lower right by the Don River and the Nile. Europe and Africa were separated by the Mediterranean Sea. These maps are known as T–O maps – the rivers and Mediterranean forming a rough T shape and the oceans surrounding the landmasses forming the O. The second schema was a circle with north at the top and, within the circle, temperature zones that included the torrid one along the equator, bordered by the temperate zones, which in turn were bordered by frigid zones at the poles. Route maps of the time carried far more detail than these schematic world maps, but the most remarkable detail and the most scientific approach was found in the portolan charts. These maps were used in navigation, primarily in the Mediterranean Sea, and showed intricate coastlines with hundreds of identified coastal locations. At several locations within the water are compass roses with direction lines extending from them.

Cartography in the Islamic world during the European Middle Ages, while varied, included continuation of the Greek scientific tradition. The scientific instrument called the astrolabe, a device for measuring angles to stars, was important in finding the way to Mecca. In the early 1400s, Ptolemy's *Geographia*, which had been preserved in Byzantium, reached Italy via refugees fleeing the invading Turks. Translated into Latin, the work had an extraordinary influence on subsequent development of cartography. Systematic projection of the spherical Earth to the flat map followed Ptolemaic instructions for well over a century.

Accurate mapping depends on the ability to measure both latitude and longitude accurately. Latitude, which could be measured by angles to the Sun and other heavenly bodies at specific times of the day, was far easier to measure than longitude, which depends on differences in time from one location to another. In a competition sponsored by the British government, John Harrison in the latter half of the eighteenth century produced a chronometer that could retain accurate time at sea (Sobel, 1995). It was a turning point in the accuracy of maps covering large regions of the world.

The rise of detailed scientific mapping of the Earth's surface in the form of topographic mapping owes much to the Cassini family, whose influence on cartography began with the appointment of astronomer Giovanni Domenico Cassini to the Académie Royale in Paris, which along with the Royal Society of London was concerned with mapping and other scientific problems. Under his direction, maps recorded only locations that were determined by astronomical methods, and detailed measurement of a degree of latitude was undertaken at various locations to test the theory of the Earth as a prolate spheroid, which affects the placement of locations on flat maps. The detailed mapping of France was continued under three more generations of the Cassinis (Jacque, César-François, and Jean) and was completed in 1793.

In the eighteenth and early nineteenth centuries, one of the most important developments in cartography was the mapping of thematic data (Robinson, 1982). With the practice of accurate base maps established, it was feasible to focus attention on the spatial arrangement of various phenomena of interest such as elevation, population, and winds. Symbol systems such as isolines, dots, and the choropleth method came into being and are commonplace in modern mapping.

Changes in cartography in the twentieth century included the use of aerial photographs in topographic mapping and changes in production technologies. The latter half of the century saw the development of satellite sensing for gathering data for maps, the deployment of global positioning systems (constellations of satellites sending signals from which latitude and longitude are determined), and the infusion of computers into mapping, including the development of geographic information systems and Internet mapping. The variety of thematic mapping methods has recently undergone rapid change as attention has focused on the use of computers to overlay multiple phenomena, produce animated maps, and develop sophisticated visualizations of spatial phenomena (Thrower, 1996).

The richness of cartographic history throughout the world and over many centuries is reflected in *The History of Cartography*, a monumental multivolume series, which continues production as this encyclopedia is being written (Harley and Woodward, 1987; History of Cartography, 2014). The project itself is an important intellectual event in cartographic history.

Case Method and Case Study Collections

Kirsten Lundberg, Columbia University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

An introduction to the case method (CM) of teaching, its history, and a representative list of global case collections focused on the disciplines of public policy, public health, journalism, environment, and other social sciences. The CM, also known as discussion-based learning, is a powerful, interactive, and student-centered teaching tool in the physical or online classroom. 'Teaching' case studies are ready-made curricula.

What Is Case Method?

The case method (CM) of instruction has existed, in one form or another, since ancient Greece. Socrates was renowned for his approach to teaching: instead of lecturing, he engaged his listeners in a give-and-take dialogue. (Example is often given of the dialogue called Meno, in which Socrates through questions leads Meno, a self-declared expert on virtue, to the uncomfortable acknowledgment that he is not sure what virtue is. See: http://classics.mit.edu/Plato/meno.html.) The so-called Socratic method became the backbone of the CM of teaching, which emerged in the nineteenth century at Harvard Law School and was adapted in the 1920s by Harvard Business School (HBS). (For a précis of the history of CM in teaching law, business, and medicine see Garvin (2003).) While law school cases concerned legal case law, HBS applied the teaching approach to professional challenges. Its cases were not hypothetical but based on practitioners' efforts to resolve some of the thorniest dilemmas of the profession.

By the 1960s, the CM had become the predominant pedagogical approach at business schools around the globe. As INSEAD, a leading global business school, put it: "The case method challenges students to use problem-solving, decision-making skills just as they would in the workplace. The approach fosters teamwork, individual reflection and active participation." (INSEAD Web site. See: http://www.insead.edu/facultyresearch/research/insead_cases.cfm.)

As word of its appeal spread, the teaching approach – alternatively called active learning, participant-centered learning, or discussion-based learning – moved slowly into other disciplines. By the early twenty-first century, it was in use to varying degrees at schools of public policy, public health, education, military training, medicine, religion, physical sciences, engineering, and journalism. T. Grandon Gill, a professor of information systems and decision sciences at the University of South Florida, wrote that CM is especially relevant when students are or will soon become professional practitioners. He said:

> The "real world" tends to produce complexity as the needs of stakeholders collide in a way that makes "fit", rather than "optimization" the most relevant goal. Where fit is the goal, judgment is nearly always required. And the case method is well suited to presenting situations where judgment is needed.
>
> Gill, 2011

CM in the Classroom

The Aim of CM

The CM won its growing legion of adherents, thanks to its powerful effect in the classroom. But what is it? It is perhaps easier to define what it is not: CM is not a lecture, not a problem set, and not a small-group discussion. Rather, it features a faculty-guided discussion based on a close, pre-class reading of a case. Students are encouraged to speak more than the instructor, to debate with one another rather than respond directly to the teacher, and to provide substantive explanations for the arguments they advanced.

Under the CM model, faculty serves not as the source of correct answers, but as discussion guides. Students, for their part, are no longer empty vessels into which learned professors pour knowledge (the lecture model) but are instead active participants in their own learning. As David Garvin of HBS puts it in an essay on case teaching: "Only if teachers and students work as partners will the true ends of education—the ability to use knowledge, to think creatively, and to continue learning on one's own—be achieved" (Christensen et al., 1991: p. 5). Students are asked to think for themselves and be on their feet to analyze, hypothesize, prescribe, and defend. Garvin's colleague C. Roland Christensen wrote:

> The discussion process itself requires students to become profoundly and actively involved in their own learning, to discover for themselves rather than accept verbal or written pronouncements. They must explore the intellectual terrain without maps, step by step, blazing trails, struggling past obstacles, dealing with disappointments.
>
> Christensen et al., 1991: pp. 16–17

CM asks students to learn at three levels: cognitive, behavioral, and personal. It strengthens both their subject-specific and transferable skills. The Australia and New Zealand School of Government (ANZSOG) says that "… the power of case teaching comes from the fact that it gives practical shape and illustration to concepts. It focuses on people as decision makers, so class participants can 'stand in the shoes' of the manager whose circumstances or dilemma are described in the case." (See the ANZSOG Web site: http://casestudies.anzsog.edu.au/.) Case use can be flexible, according to the preference of the instructor: in some courses,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41003-2

cases feature in every class; in others, students might discuss only one.

Effectiveness of CM in Classroom Discussions

During case discussions, students come to understand that the world is not black and white, but gray, and that throughout history, most decisions are far from preordained. Rather, history is made by ordinary individuals making the best choice they can in spite of significant deficits. Typically, decision makers don't have enough money, personnel, time, and – most crucially – information. Nonetheless, they must act. Case discussion provides students with a vicarious workplace experience. While the effectiveness of CM has been under researched, one study found that it increases students' tolerance for ambiguity (Banning, 2003). In a world characterized by rapid change and a need for flexibility, this was a powerful outcome.

CM has proved effective in multiple fields. The National Center for Case Study Teaching in Science, for example, found it invaluable in teaching the hard sciences. As the Center says, "… cases can be used not only to teach scientific concepts and content, but also process skills and critical thinking." Moreover,

> Since many of the best cases are based on contemporary, and often contentious, science problems that students encounter in the news, the use of cases in the classroom makes science relevant. We have also found the method to be extraordinarily flexible. We have seen it used as the core of entire courses or for single experiences in otherwise traditional lecture and lab courses. Moreover, cases can be presented in a variety of formats and taught in a variety of ways, ranging from the classical discussion method used in business and law schools to Problem-Based Learning and Team Learning, with their emphasis on small-group, cooperative learning strategies.
>
> See the Center's Web site: http://sciencecases.lib.buffalo.edu/cs/about/

'Teaching' Cases

Definition of 'Teaching' Case

An essential component of CM is the case study. Multiple definitions of the term 'case study' have long muddied public understanding of how a case is used in teaching. For example, 'case study' in popular parlance usually means an example of best practices; it can also refer to an academic analysis.

But what has became known as a 'teaching case' (to differentiate it from the others) is not an analysis of a situation, nor a description of best practices. It is a real-life story intended as a vehicle for classroom discussion. A teaching case describes a situation; it does not prescribe a solution. It provides a snapshot of a specific incident which, through discussion, illuminates larger principles. A teaching case engages students so they can practice how to take action. It introduces students to the realities of their chosen profession. It also tests students' ability to apply theory to a real-world situation.

Even with that clarification, practitioners differ on what constitutes a teaching case. Consensus has settled around three broad categories: decision forcing, retrospective, and point of view. Decision-forcing cases are by far the most popular kind of teaching case and, many would argue, the most effective in the classroom. A decision-forcing case puts students in the shoes of a protagonist confronting a thorny dilemma to which there was (1) no single correct answer and (2) a range of equally viable solutions. A fully researched, interview-based case describes the wide range of constraints – political, economic, and personal – and stops at the point where a decision is imminent. Students are asked to discuss what they would do in his or her place.

In contrast, a retrospective or research case (or 'cadaver case,' as a former case program director termed it) looks at a case incident in its entirety, from inception to resolution. Instead of placing students in a decision-making role, it asks them to look back at a concluded episode, identify the turning points, speculate on what might have been done differently, and try to rethink the outcome. Finally, a point-of-view case tells a story from a single point of view. It is useful when a more comprehensive case is impossible for logistical or political reasons – for example, a case based on a political dissident in an authoritarian regime. All three types of cases can, if necessary, be complimented by secondary sources.

'Teaching' Case Design

There is considerable controversy over whether a teaching case should be hypothetical, disguised (names and other details fictionalized), a simulation, or a hybrid. Purists insist that the best cases are real stories about real people, that fact trumps fiction in nearly every instance, and that students cannot easily dismiss a reality-based case as 'implausible' because it did, in fact, happen. One introduction to a collection of teaching cases argues:

> (Cases) … based on actual events tend to be more effective than the ones that are made up. This is because fictitious cases often tend to be too neat and too comprehensive… Unfortunately, life … is typically messy and the information available to decision makers at any given time is neither comprehensive nor logically cohesive.
>
> Brynard and Erasmus, 1995: p. 7

Moreover, real cases based on primary sources (interviews) serve a second function as 'microhistory,' or the history of how decisions are made. Cases can be an important resource for future historians because they chronicle the minutiae of what leaders considered in coming to decisions about crucial aspects of the field.

Many faculties, however, routinely use and express professional satisfaction with hypotheticals, disguised cases, simulations, and hybrids. These are especially useful in dealing with incidents considered too sensitive to discuss on record by the participants as it is. Yet another category sometimes termed as 'case study' is an assembly of raw materials such as newspaper articles, which students read in preparation for a class discussion. (For an interesting review of case classroom challenges from the faculty point of view, see the collection of more than 150 short case studies written by economics teaching staff hosted by The Economics Network at the University of Bristol (UK): http://www.economicsnetwork.ac.uk/showcase.)

Case Examples

There is no single case that can serve as an example of all the possible approaches to writing a case. But a good teaching case tells a story, raises discussions of a range of topics, and stops at a decision or a turning point. Here are two examples of decision-forcing cases. One is a journalism case; the other about public health. Each could be used in other disciplines as well, such as public policy, international relations, conflict studies, or crisis management.

Case Example 1

In January 2006, assailants kidnapped Jill Carroll, a stringer in Iraq for the *Christian Science Monitor*. The case tracks the *Monitor's* editorial leadership over the next 2 months as they struggle to manage their multiple constituents: the State Department, the Baghdad bureau, the Arab press, the US Central Intelligence Agency (CIA), the Federal Bureau of Investigation (FBI), Carroll's family members, and so forth. It ends as the *Monitor* prepares a public service announcement (PSA) to run on Al Jazeera pleading for information about Carroll. The FBI has advised the *Monitor* to stay under the radar to secure Carroll's release, while the CIA has advised it to publicize her plight widely. The decision point: should the *Monitor* run the PSA?

The case discussion will cover far more than what to do about the PSA. Under the skillful guidance of an instructor, students can talk about how a news organization, which usually covers the problems of others, manages an internal crisis; how to negotiate with a wide range of stakeholders or constituents; how to report in conflict situations; and what obligations a news organization might have to a stringer in a war situation.

Case Example 2

In October 2012, as Superstorm Sandy approached the East Coast, the North Shore-Long Island Jewish Hospitals (North Shore-LIJ) network braced for landfall. The network owned three hospitals in low-lying areas; just a year earlier, during Hurricane Irene, it had evacuated those hospitals. But Irene veered off and the expensive evacuations were for naught. The decision point: should North Shore-LIJ evacuate this time?

The case discussion addresses this very question. But the case document also allows students to explore the legal and ethical trade-offs between evacuating patients and sheltering in place, the role of hospitals during a natural disaster, the relationship between a private hospital network and its government overseers, the characteristics of emergency management, and what kind of decision-making structure works best in a disaster?

Case Example Reuse

These are only two examples. There exist thousands of cases about thousands of topics. Some are narrowly conceived to serve in a specific class; others can be used in a variety of courses and classes. Good cases can have a shelf life of many years. With good writing and a strong conceptual approach, the case 'incident' becomes a snapshot which captures reality for a moment, and raises a discussion on a range of higher level issues grounded in the reality of the original event.

Many cases have epilogues; some have teaching notes as well. What actually happens in a case should not matter to its pedagogical usefulness. If students are asked to put themselves in the shoes of the decision maker *at that time*, they will engage with the dilemma regardless of the eventual outcome. What happened was simply the choice made on the spot; the case does not speak to if that choice was the only, the best, or the most beneficial to all parties.

Levels of Learning

In the course of preparing for and discussing a case in the classroom, students typically learn at three levels simultaneously: factual material, behavioral/analytical, and personal. The first level is cognitive: students absorb information about the subject treated in the case, be it the history of government/media relations in a given country or the details of an aid project in Haiti or the factors an engineering firm considered in determining where to site a bridge. Such knowledge is most easily acquired and, often, most quickly forgotten.

The related analytical skills, however, last a lifetime. Preparing for and discussing a case require students to go through five steps. The first is analysis: what is going on here? Whose problem is it, and are there shared interests? The second is diagnosis: what are the available options for a solution? Third, students are asked to anticipate consequences of options and weigh the respective pros/cons. Fourth, they must prescribe a solution to the dilemma and fifth, defend it (or allow themselves to be persuaded by others). Taken together, these steps help students exercise and strengthen their skills of judgment, and of critical thinking.

In his classic article on why CM outperformed lectures, HBS professor Charles I. Gragg memorably explained in the title: 'Because wisdom can't be told' (Gragg, 1954: p. 6). Subsequent research reinforces the view that students retain the longest what they teach themselves. According to Professor Clyde Freeman Herreid of the University at Buffalo (NY), who has written extensively on the use of CM in science teaching:

> If reading, arguing, and challenging are hallmarks of critical thinking, then case studies are the poster children for the process. Most of them are discipline specific, certainly. But they all grapple with the essence of critical thinking—asking for evidence—developing a habit of mind that should permeate everyday life.
>
> Herreid, 2004

Students also acquire lifelong behavioral skills in a case classroom. In the course of discussing a case, they practice negotiation and public speaking. They often have the chance to work in teams. They learn how to persuade others, and also the value of listening – of being willing to change one's mind in the face of a convincing argument. These skills will serve them well in whatever field they choose, and they are unlikely to forget them.

At the deepest level, case discussions are able to help students confront their own biases and prejudices. Not necessarily the big issues such as racism or sexism, but smaller ones: that growing up in a suburb might lead one to think differently than someone who grew up on a farm or that socioeconomic differences can influence one's world view. Students in case classrooms are routinely surprised that a problem whose solution they deemed 'obvious' inspired a very different solution from fellow students. No matter the field, a better understanding of one's personal history and social context helps guard against an emotional, knee–jerk reaction to professional situations. A skillfully guided case discussion could lead to valuable self-discovery.

Case Collections

Below is a list of case collections useful to instructors in the behavioral and social sciences. A few, such as science and engineering, may seem outside the disciplinary limits. But they are included because the cases by and large focus on aspects of those fields that overlap with behavioral and social science concerns.

While every effort has been made to discover case programs around the world, this list does not pretend to be comprehensive. Some of the collections make their cases available to the public for free, others charge, and a third group may require a personal request to acquire a case. See each individual Web site for detailed information.

Case Consortium @ Columbia, Columbia University, New York, NY (https://casestudies.jrn.columbia.edu)

This collection of multidisciplinary, online, multimedia cases started in 2007, with a focus on journalism. By 2013, it included upwards of 60 cases for use in a variety of disciplines, including public health, public policy, journalism, and sustainable development. The Case Consortium's mission is to produce excellent, case-based curricula for disciplines outside business, based on the view that students in all professional fields should have the opportunity to benefit from CM. The cases are free to registered faculty and are available for a fee to other users. The Web site offers guidelines on how to use cases in the classroom. The consortium also offers custom training to case teachers and writers.

Case Method Project, US Marine Corps University (MCU), Quantico, VA (http://guides.grc.usmcu.edu/content.php?pid=273794&sid=2339824)

The Case Method Project at MCU started as a one-person project in December 2007. By 2013, its 100+ cases were being used in a variety of programs throughout the Marine Corps. Instructors developed and taught their own cases, both in the US and globally. Some cases are based on original research but most came from secondary sources. The decision-forcing cases give the US Marines practice in solving a wide variety of problems, most of which defied conventional categories. They also encourage Marines to engage in the serious study of history. Besides decision-forcing cases, the project produced 'conference-style' cases, so-called because participants were not expected to prepare in advance but to learn about the case dilemma in the classroom. Finally, hybrid cases provided some background prior to class, and some in class.

Case Program, ANZSOG, Melbourne, Australia (www.casestudies.anzsog.edu.au)

The ANZSOG case collection, established in 2004, celebrated the publication of its 150th case study in August 2013. Its public sector cases focus on a range of issues in Australia and New Zealand, from accountability to policy development and disaster management. ANZSOG was established in 2002 as a unique initiative of governments, universities, and business schools to educate future public sector leaders in public policy and management. Case teaching is an integral part of its interactive pedagogical style. The program also offers workshops on case teaching and writing.

Case Program, Harvard Kennedy School, Cambridge, MA (www.ksgcase.harvard.edu)

The Case Program's collection of public policy cases numbered over 2000 by 2013. The cases cover a wide range of public policy topics, from health to national security, nonprofits, crisis/risk management, economics, public/private partnerships, intelligence, international relations, and public management. The online collection dates back to 1974, and includes principally decision-forcing and retrospective cases. The cases are free to registered faculty and are available for a fee to other users. The Web site includes guides to how to learn and teach using the CM.

Case Study Program, The Institute of Public Administration of Canada (IPAC), Toronto, Canada (http://www.ipac.ca/CaseStudyProgram-About)

The IPAC Case Study Program is Canada's premier portal to case study material for both teachers and public organizations. Founded in the late 1970s, the case inventory, as of 2013, included over 200 cases. The program offers a variety of services designed to foster the use and creation of case studies either through academics who share cases they use in class or via new cases based on real-life experiences at public organizations. The cases are public-sector oriented, and include decision-forcing cases, simulations, and knowledge transfer (sharing lessons learned). They are available electronically for a fee; free to IPAC members.

Case Study Unit, Lee Kuan Yew School of Public Policy, University of Singapore (http://lkyspp.nus.edu.sg/research-centres/publications/case-studies/)

This small collection of 20 cases covers a wide range of topics about public policy and public administration in Asia: foreign policy, health care and education, environment and climate change, leadership and public management, and others. Some are based on primary, others on secondary, sources of information. The cases are all based on real events, but in some instances details are disguised for teaching purposes. The cases

have been used in one or more of the master's degree programs at the school, as well as in executive education programs. Teaching notes exist for most of the cases. They are freely available on the Web site.

Centre for Social Investment, Heidelberg University, Germany (http://www.thecasecentre.org/educators/ordering/whatsavailable/collections/csi)

The Centre for Social Investment (https://www.csi.uni-heidelberg.de/) was founded in 2006 as an academic institute of Heidelberg University (economics, social science, law, and theological faculties). By 2013, its case collection held about 40 cases (plus teaching notes) about nonprofit management. The cases are based on two research projects: Strategies for Impact in Philanthropy (https://www.csi.uni-heidelberg.de/projekte_sip_e.htm) and Strategies for Impact in Education (https://www.csi.uni-heidelberg.de/projekte_sie_e.htm). The Center aims to improve understanding of social investment, civil society, social economy, and philanthropic institutions, and to inform about the policymaking that affected them.

China Case Center for Public Policy & Management (CCCPPM), Tsinghua University, Beijing (http://www.sppm.tsinghua.edu.cn/english/research/case/)

The China Case Center was founded in July 2004. Its goal is to produce cases for the School of Public Policy & Management in order to improve the quality of teaching and to train professional public managers. The Center also holds seminars on case teaching and writing to promote use of the CM among its faculty. The Center makes its cases available for a fee to other master of public administration programs in China. It also hosts an online forum for instructors to share case teaching experiences.

Electronic Hallway, University of Washington (http://hallway.evans.washington.edu/)

The Electronic Hallway at the Evans School of Public Affairs, University of Washington, is an online library of teaching cases and other curricular materials for faculties who teach public administration, public policy, and related subjects. The Hallway is a membership organization; cases are submitted by member faculties. Cases are grouped according to their organizational setting or policy area, such as arts and culture, nonprofit and NGOs, or law enforcement and corrections. The cases are sold around the world to graduate, undergraduate, and government training programs. The Hallway also runs short courses on CM.

Enduring Legacies Native Cases, Evergreen State College, Olympia, WA (http://nativecases.evergreen.edu/index.html)

This collection of free, decision-forcing cases examines Native American issues, including biology, economics, chemistry, environmental studies, ethics, health, women's studies, and natural resources, among others. The collection, which numbered over 80 by 2013, began in 2006 as a partnership between Evergreen State College, Northwest Indian College, Salish Kootenai College, and Grays Harbor College. Its goal is to develop and disseminate curricula and teaching resources about key issues in Indian Country. It has support from the Lumina Foundation for Education, the Bill and Melinda Gates Foundation, and the National Science Foundation. An Indian Advisory Board helps identify key issues.

Engineering Case Program, Rose-Hulman Institute of Technology, Terre Haute, IN (http://www.civeng.carleton.ca/ECL/5index.html)

The Engineering Case Program, which features accounts of real engineering work, originated at the Stanford University in 1964 with the support of the National Science Foundation. It continued under the sponsorship of the American Society for Engineering Education (ASEE). The Rose-Hulman Institute of Technology houses a collection of some 250 cases, and is in charge of distribution. ASEE jointly administers the Case Program with Rose-Hulman.

EnviroDx-Clinical Cases in Environmental Medicine, University of Utah (http://library.med.utah.edu/envirodx/index.html)

This innovative and small collection of four cases addresses environmentally related diseases. In the computer-based cases, the user is put in the role of a physician treating a patient with an unknown disease or condition possibly caused by exposure to environmental factors. The cases were developed by a team of content experts, instructional designers, graphic artists, multimedia producers, and programmers. The cases are designed to help students develop diagnostic and treatment skills, as well as obtaining relevant and reliable information quickly.

E-PARCC, Collaborative Governance Initiative, Program for the Advancement of Research on Conflict and Collaboration, Maxwell School, Syracuse University, New York (http://www.maxwell.syr.edu/parcc_eparcc.aspx)

E-PARCC is an open (Creative Commons license) online resource for those teaching the skills and concepts of collaborative governance: public management, networks and public management, collaborative governance, and collaborative problem solving. The Web site includes case studies about real-world occurrences, and simulations that engage students in collaborative problem-solving. Materials in the collection are selected through an annual competition, and are double-blind peer reviewed.

Epidemiologic Case Studies, Centers for Disease Control, Atlanta, GA (http://www.cdc.gov/epicasestudies/classroom_noro.html)

This small collection of eight interactive case studies was created to teach epidemiologic principles and practices. Based on real-life outbreaks and public health problems, they were developed in collaboration with the original

investigators and experts from the Centers for Disease Control and Prevention. The case studies require students to apply their knowledge and skills to the kinds of problems confronted daily by public health practitioners at the local, state, and national level.

Global Health Delivery (GHD) Project, Harvard University, Cambridge, MA (http://www.thecasecentre.org/educators/casemethod/resources/freecases/ghd)

The GHD Project (http://www.globalhealthdelivery.org/) at Harvard University offers a series of some 30 free teaching cases that examine principles of health-care delivery in areas with few resources. Teaching notes accompany the cases. The cases allow students to examine the real-world challenges faced by global health programs and organizations that seek to deliver health care in low-resource settings. GHD is working to establish a network across disciplines to help health-care stakeholders and practitioners benefit from and build on each other's successes.

Hubert Project, University of Minnesota, Minneapolis, MN (http://www.hubertproject.org)

Publicly launched in August 2012, the Hubert Project is both a platform for public affairs educators to connect globally in transforming public affairs education and a portfolio of open-access, web-based multimedia learning materials created and shared by this community. It is governed by an international group of public affairs schools. The portfolio contains three types of multimedia learning materials: *video briefs* featuring short introductions to a public affairs issue, *curated cases* that package publicly available materials into timely and relevant mini-cases, and in-depth *e-cases* describing a critical quandary that a leader or team must resolve.

Innovations for Successful Societies (ISS), Woodrow Wilson School of Public & International Affairs and the Mamdouha S. Bobst Center for Peace and Justice, Princeton University, Princeton, NJ (http://www.princeton.edu/successfulsocieties/)

ISS cases are used by a wide variety of universities, research institutes, public policy organizations, and NGOs around the world. Its cases, usually examples of best practices, support public servants, policy makers, and scholars seeking to build effective and accountable government in challenging contexts. The cases focus on institution building and government implementation. Started on a pilot basis in 2006, as of 2013 its 100 plus+ cases deal with topics from agency transformation to citizens monitoring public services, and police services.

INSEAD Humanitarian Research Group, Fontainebleau, France (http://www.insead.edu/facultyresearch/centres/isic/humanitarian/CasesHumanitarianResearch.cfm)

Part of a business school, this small collection of 20+ cases from the Humanitarian Research Group deals with the logistics of disaster planning and research. Some cases look at disasters that made global headlines, while others examine issues of planning and response, such as transport, funding, or distributing information online. They cover subjects from organizational behavior to supply chain management, political science, ethics, negotiations, and marketing.

National Center for Case Study Teaching in Science, University at Buffalo, Buffalo, NY (http://sciencecases.lib.buffalo.edu/cs/)

The National Center for Case Study Teaching in Science at the University at Buffalo started in the late 1990s to promote the development and dissemination of materials and practices for case teaching in the sciences. In 2013, nearly 500 cases were available on their Web site for use at the graduate, undergraduate and high-school level. In addition, the center offers a 5-day summer workshop and a 2-day fall conference to train faculty in the CM of teaching science. Support for the center comes from the National Science Foundation, the Pew Charitable Trusts, and the US Department of Education. Science faculties write the cases, which are published after peer review and revision. All have teaching notes.

Pew Case Study Center, Institute for the Study of Diplomacy, Georgetown University, Washington, DC (http://faculty.guisd.org/index.cfm)

This collection of nearly 280 decision-forcing and retrospective cases at the GUISD focuses on international affairs and diplomacy. The cases are used in professional, graduate, and undergraduate courses. Twenty-one of the cases were produced under the auspices of the Carnegie Council on Ethics and International Affairs between 1990 and 2001. Cases can be ordered online; the price of a pdf version is cheaper than that of a hard copy.

School of Public Affairs and Administration Case Collection (SPAA), Rutgers University–Newark, NJ (http://spaa.newark.rutgers.edu/casesimportal/contact/295.html)

SPAA at Rutgers-Newark published cases on public and nonprofit management. Case topic areas include public/nonprofit administration, organizational theory, human resources and diversity, decision making, politics/policy-making, multi-level governance, performance measurement, budgeting and finance, leadership, and ethics. The collection includes fictionalized as well as real-world cases. Many of them are linked to multimedia sources – news, video, social networks, and others.

The Case Centre, UK (formerly ECCH: European Case Clearing House), Cranfield University, UK (www.thecasecentre.org)

The Case Centre is an independent, nonprofit, membership-based organization dedicated to promoting the CM of learning. It maintains a collection of some 49 000 cases on management. While its focus is business cases, it also holds case collections on humanitarian, charitable, political, ethical, and not-for-profit issues. It distributes many large case collections, including those at the Stanford University and Harvard's Kennedy School. It provides multiple resources on CM for instructors and runs training programs.

Abstract

Case, as traditionally understood, refers to a system of inflection, usually in the form of suffixes, which marks the relation of nouns in a clause. In the Latin sentence *Calpurnia Clodiam vīdit* 'Calpurnia saw Clodia' the fact that Clodia rather than Calpurnia is the one who is seen is signaled by the -m suffix on Clodia, rather than by word order as in English. This -m is a case suffix. Cases can be classified as grammatical (signaling a grammatical relation) or semantic (signaling a semantic role). Grammatical cases include the nominative marking the subject, the accusative marking the direct object, the dative marking the indirect object and the genitive marking a dependent of a noun. In some languages the subject of a transitive verb is distinguished by an ergative case and the subject of an intransitive verb and the direct object are treated alike, usually left unmarked in what some call the absolutive case. Semantic cases include the locative indicating location or place where (e.g., 'in,' 'at'), the allative indicating movement toward (e.g., 'to') and the ablative indicating direction from (e.g., 'from'). Case may be marked on the head of a noun phrase and on its dependents via concord, or it may be marked on only one constituent of the noun phrase, usually the last, whether the last member is the head or not.

Case, Case Form, and Case Marker

A morphological case system is a system of inflection that marks dependents for the type of relation they bear to their heads. Typically, case marks the relationship of a noun to a verb at the clause level or of a noun to a preposition, postposition, or another noun at the phrase level. Consider the following Turkish sentence:

(1)	Ali	adam-a	elma-lar-ı	ver-di
	Ali.NOM	man-DAT	apple-PL-ACC	give-PAST.3SG

'Ali gave the apples to the man.'

The suffix -ı indicates that elmalar is the direct object of the verb vermek 'to give' and the suffix -a indicates that Adam is the indirect object. The suffix -ı is said to be an accusative (or objective) case marker and the word form elmaları is said to be in the accusative case. The suffix -ı also indicates that elmalar is specific, since in Turkish only specific direct objects are marked as accusative. The suffix -a is a dative case marker. Ali contrasts with elmaları and adama in that it bears no overt suffix. It is said to be in the nominative case, which in this sentence indicates the subject.

Turkish has a system of six cases as in Table 1. The locative marks location as in Istanbul-da 'in Istanbul,' and the ablative indicates 'from' or 'out of' as in Ankara-dan 'from Ankara.' The genitive is used in phrases like adam-ın ev-i 'the man's house' where ın corresponds to 's in English. The suffix -ı on ev 'house' is a third person possessive form translatable as 'his,' 'her,' or 'its.' In Turkish 'the man's house' is literally 'the man's, his house.'

Table 1 Turkish case system

Nominative	adam
Accusative	adamı
Genitive	adamın
Dative	adama
Locative	adamda
Ablative	adamdan

The word forms displayed in Table 1 make up a paradigm, that is, they constitute the set of case forms in which the lexeme *adam* can appear. In Turkish one could say that there is only one paradigm in that a single set of endings is found for all nouns, although these suffixes do undergo some phonologically conditioned changes such as undergoing vowel harmony and the like. The locative, for instance, has the form-da following stems with back vowels and -de following stems with front vowels. A distinction needs to be made between cases (of which there are six in a system of oppositions), and the case markers or case forms through which the cases are realized. A case marker is an affix and a case form is a complete word. In Turkish the case affixes can be separated from the stem, so it is possible to talk about case markers. In some languages, however, it is not possible to isolate a case suffix, so it is necessary to talk in terms of the various word forms that express the cases of the stem. These are case forms.

Case Marking Fused with Number and Gender

The traditional notion of cases and the associated terminology were developed on the basis of Ancient Greek and Latin where it is not possible to separate number marking from case marking. This means separate paradigms for the two number categories, singular and plural. Moreover, there are different case/number markers for different stem classes. In Latin five such classes are recognized, or five declensions as they are called. The three major declensions are illustrated in Table 2.

In Latin there is also a three-way gender distinction: masculine, feminine, and neuter. With a few exceptions male creatures are masculine and females feminine, but inanimates are scattered over all three genders (though almost all neuter nouns are inanimate). There is a partial association of form and gender in that ā-stems are almost all feminine and *o*-stems mostly masculine (except for a subclass of neuters represented by bellum in Table 2). This means that there can be fusion of

Table 2 Latin case paradigms

	1	*2*		*3a*	*3b*
	ā-stems	o-stems		cons. stems	i-stems
	Feminine	Masculine	Neuter		
	domina	dominus	bellum	cōnsul	cīvis
	'Mistress'	'Master'	'War'	'Consul'	'Citizen'
Singular					
Nominative	domina	dominus	bellum	cōnsul	cīvis
Vocative	domina	domine	bellum	cōnsul	cīvis
Accusative	dominam	dominum	bellum	cōnsulem	cīvem
Genitive	dominae	dominī	bellī	cōnsulis	cīvīs
Dative	dominae	dominō	bellō	cōnsulī	cīvī
Ablative	dominā	dominō	bellō	cōnsule	cīvī, cīve
Plural					
Nominative	dominae	dominī	bella	cōnsulēs	cīvēs
Vocative	dominae	dominī	bella	cōnsulēs	cīvēs
Accusative	dominās	dominōs	bella	cōnsulēs	cīvīs, cīvēs
Genitive	dominārum	dominōrum	bellōrum	cōnsulum	cīvium
Dative	dominīs	dominīs	bellīs	cōnsulibus	cīvibus
Ablative	dominīs	dominīs	bellīs	cōsulibus	cīvibus

gender, number, and case. The point is illustrated in Table 2 where we have *domina* 'mistress (of a household)' illustrating feminine ā-stems and *dominus* 'master (of a household),' which is based on the same root, representing masculine o-stems. As can be seen from Table 2 the word form *domina* simultaneously represents nominative case, feminine gender, and singular number, *dominum* represents accusative case, masculine gender, and singular number, and similarly with other word forms.

Where there is more than one paradigm, it frequently happens that distinctions made in one paradigm are syncretized or neutralized in others. In the traditional descriptions a case is established wherever there is a distinction for any single class of nominals. Informally one might consider that a case is a row in a set of paradigms like those in Table 2. Dealing in cases ('rows') facilitates the description of the relation of form and function. A particular case can be said to have one or more functions without reference to the details of the forms.

The functions of the cases in Latin, and in Ancient Greek, are important in that they have served as a model for applying case labels in other languages such as Turkish. In Latin the nominative encodes the subject and the accusative the direct object. The dative marks the indirect object of a few three-place verbs such as dare 'to give' and the complement of a few two-place verbs including crēdere 'to believe,' nocēre 'to be harmful to,' and subvenīre 'to help.' The genitive is used mainly to mark noun phrases as dependents of nouns, in particular to mark the possessor: cōnsulis equus 'the consul's horse.'

The ablative in Latin represents the syncretism or merger of three once-distinct cases: the ablative, the locative, and the instrumental so it is not surprising then to find that it expresses source, location, and instrument.

The vocative is anomalous in that it does not mark the relationship of dependents, but is used as a form of address as in Quō vādis, domine? (whither go.2SG lord. VOC) 'Where are you going, master?' However, the vocative belongs with the other cases since its marking belongs to the same system as the unequivocal cases.

Latin uses a system of prepositions in addition to the case system. Some prepositions, including all those expressing destination, such as ad 'to' govern the accusative (ad urbem 'to the city'), while others such as ex 'out of, from' govern the ablative (ex urbe 'from the city').

The Range of Case Systems

Case systems differ in terms of the number of distinctions they make and range from a minimum of two as in some Iranian languages, which have a nominative and an oblique, to figures like 15 in Finnish (see Table 3).

Case systems also vary in terms of the type of distinction they make in a given domain. While many languages are like Latin in having one case for the subject, namely the nominative, and another case for the direct object (the accusative), some languages including Basque, northeast Caucasian languages, and many Australian languages have one case for the subject of a transitive verb, which is called the ergative, and another case to cover the subject of an intransitive predicate and the direct object. This case is generally morphologically unmarked. Some writers call this case the absolutive; others call it the nominative. The following illustration is from the Australian language Kalkutungu where the ergative is realized by the suffix -yu and the absolutive/nominative is unmarked. Note, however, that with the cross-referencing clitics that are attached to the purposive auxiliary a common from represents the subject and a distinct form the object.

(2) Nhutu a=nhurr ingka?
you.NOM PURP=2PL.SUBJ go
'Are you mob going?'

(3) Nhutu-yu a=nhurr nuwa puyu?
you-ERG PURP=2PL.SUBJ see 2DU.NOM
'Are you mob going to see them two?'

(4) Nhutu a=kutu nuwa puyu-yu
you.NOM PURP=2PL.OBJ see 2DU-ERG
'They two want to see you mob.'

In a number of languages, particularly in Australia, accusative and ergative marking are found in the same language. As pointed out by Silverstein (1976), there tends to be some complementarity with ergative marking confined to nouns

Table 3 Finnish local cases

	Location	*Source*	*Destination*
Ø	-na	-ta	-ksi
	essive	partitive	translative
Interior	-ssa	-sta	-(h)Vn, -sVVn
	inessive	elative	illative
	'In'	'From (inside)'	'Into'
Exterior	-lla	-lta	-lle
	adessive	ablative	allative
	'At'	'From (outside)'	'To(wards)'

and accusative to pronouns or to pronouns plus certain classes of noun such as kinship nouns, personal names or in some instances all human nouns. The following paradigms from another Australian language, Yuwaalaray, show ergative marking with nouns and accusative with pronouns (see Table 4).

Every language has to provide for the expression of a large number of local notions. This can be done via adpositions as with English prepositions such as on, to, over, and under. Where a number of local notions are expressed via the case system the number of cases naturally rises. In Finnish, for instance, the notions of location, source, and destination can combine with the notions of interior and exterior to produce a set of nine local cases as illustrated in Table 3. Originally there were two systems (location, destination, and source) and (interior, exterior, and neither), but the markers have partially fused. The functions are no longer entirely local either. The partitive is used for the patient if it represents part of a whole or an indefinite quantity, or if the action is incomplete, or if the polarity of the clause is negative. The translative refers to the endpoint of a transformation as in 'She turned the frog into a prince.'

Other cases commonly encountered include the comitative, expressing accompaniment (I went with them) and instrumental expressing the instrument used to carry out an action (She wiped the screen with a cloth). In the Uralic languages a case called abessive is found. It means 'without,' 'not having.' In Finnish, for instance, rahta-tta is (money-AB) 'moneyless.'

Classifying Cases

The Greeks made a primary distinction between the nominative and the other cases, collectively called the oblique cases. This makes sense when one considers that the nominative was the form used in isolation, whereas the other forms generally required a particular syntactic context. In some languages there is a formal distinction between the nominative and the oblique cases inasmuch as there is a special stem for the obliques. This is the situation in many Dravidian and northeast Caucasian languages, for instance. In most languages the nominative bears no marking as in Turkish (Table 1), but consists of the bare stem. Indo-European case languages are unusual in having a marked nominative in most paradigms (Table 2).

Another distinction that is often made is between grammatical (or syntactic) cases and semantic (or concrete) cases. The grammatical cases are traditionally taken to include the nominative and accusative and often the genitive, and should include the dative and the ergative. The basis for the distinction is often not made clear, but if the criterion for classifying a case as grammatical or syntactic is that it expresses a purely syntactic as opposed to semantic relation, then the dative and ergative should certainly be included since the dative encodes the indirect object and the ergative encodes the 'transitive subject.'

If the distinction between grammatical and semantic cases were to be clear-cut, the grammatical cases would encode only purely syntactic relations and the semantic cases would encode only homogeneous semantic relations such as location or source. However, it is common for a syntactic case to encode a semantic relation or role that lies outside of whatever syntactic relation it expresses. In Latin, for instance, the accusative not only expresses the direct object, it also expresses the semantic role of destination as in Vādō Rōmam 'I am going to Rome.' On the other hand, there are situations where the so-called semantic cases encode a purely syntactic relation. This commonly occurs with the passive where the demoted subject is often expressed via a semantic case. In Latin the demoted subject is encoded in the ablative as in vīsus ā cōnsule 'seen by the consul.'

It is also convenient for the purposes of making certain generalizations to distinguish the cases that encode the complements (including the subject) of typical one-place and two-place transitive verbs. These are the nominative, ergative and accusative, and they are known collectively as the core cases and the others as peripheral cases. In Hindi-Urdu and other Indo-Aryan languages a single case is used for subjects and objects and it is called the direct case as opposed to the oblique case. In some treatments the term local cases is used to cover cases designating notions of place such as location, source, destination or path (Table 3).

Table 4 Yuwaalaray case marking

Nominative	dhayn 'man'	ngali 'we two'
Ergative/instrumental	dhayndu	ngali
Accusative	dhayn	ngalinya
Genitive	dhayn.gu	ngalingu
Dative	dhaynda	ngalingunda
Ablative	dhayndi	ngalingundi

Exponence

The relation between the verb and its dependents, whether complements or adjuncts, may be expressed by an adposition, either a preposition as in English or a postposition as in Turkish. In languages with morphological case systems there are usually adpositions as well as cases. In Latin, as we have seen, there are prepositions, and in Turkish there are postpositions such as sonra 'after,' which governs the ablative: tiyatrodan sonra (theatre-ABL from) 'after the theater.' In such languages there are essentially two systems: an inner, restricted system of case and an outer, more elaborate system of adpositions. In some languages such as Japanese there is just one system of postpositions, which includes markers for subject, direct object, indirect object, and topic, as well as for local notions such as 'from.' In such a language the distinction between case and adposition is essentially neutralized. In the following Japanese example ga marks the subject, ni marks the indirect object, and o marks the direct object.

(5) Sensei ga Tasaku ni hon o yat-ta
teacher SUBJ Tasaku IO book DO give-PAST
'The teacher gave Tasaku a book.'

Morphological case is almost always realized as a set of suffixes, though there are instances where there is some

mutation of the stem as with Old English fēt, the dative singular (as well as nominative and accusative plural) of fōt 'foot,' tone, as in some western Bantu languages, or complete suppletion as with the English pronouns: I/me, she/her, we/us, and also he/him and they/'em/them where there is an -m suffix (historically dative) plus some stem alternation.

Where categories such as number, gender or possessor are marked as well as case and where these categories are not fused, case marking normally follows these other categories as in Turkish: adam-lar-ım-la (man-PL-1SG.POSS-LOC) 'with my men' where the number marking and possessor precede the case marking.

Within the noun phrase there are two common distributions for case marking. Either it occurs on all types of nominal or it is occurs on only one word. In the former type the distribution is traditionally described in terms of dependents showing case concord or agreement with a noun head. In the following example from Ancient Greek bios is a nominative singular form of a second declension (o-stem) masculine noun, the nominative indicating that bios is the subject of the predicate. The definite article and the adjective are in the nominative singular masculine form, their concord in case, number and gender indicating that they are dependents of bios.

(6) Ho aneksetastos bios ou biōtos anthrōpō
the.NOM.SG unexamined.NOM.SG life.NOM.SG not livable.NOM.SG man.DAT.SG
'The unexamined life is not livable for man.'

This example also illustrates concord between a predicative adjective (biōtos) and the subject (bios). While concord of case, number, and gender of predicative adjectives is the norm in Latin and Ancient Greek [GJ1], as well as in some modern languages such as Slavic languages (some of which have 7 cases), in many other languages predicative adjectives display no concord. This is the situation in German where the predicative adjective consists of the bare stem and is distinct from the various case forms.

Full case concord within the noun phrase is found in the older Indo-European languages and in some modern branches including Romance and Slavic. In Polish, for instance, *ta piękna biała róża*, 'this beautiful white rose' NOM versus *tej pięknej białej róży* 'of this beautiful white rose' GEN. It is also found in Balto-Finnic, Slavic, Semitic [GJ2], in some Australian languages, and elsewhere, but it is a minority system. In some languages such as Hungarian the concord does not extend to the adjective and in the Indo-Aryan languages adjectives exhibit fewer case distinctions than nouns. In the more conservative Germanic languages, including modern German, the adjective shows fewer case marking distinctions where a determiner is present. In most languages case concord does not extend to dependents in the genitive case. However, in Georgian a postposed genitive exhibits concord, which results in double case marking: compare davit-is mama-s (David-GEN father-DAT) and mama-s davit-isa-s (father-DAT David-GEN-DAT 'to David's father'). Where case marking occurs on only one word in the noun phrase, it is usually on the final word. In many languages, including a vast number in northern Asia and South Asia, the final word is the head noun in the noun phrase. The following example is from the Dravidian language Kannada:

(7) Naanu ellaa maanava janaangavannu priitisutteene
I.NOM all human community.acc love.1SG
'I love all mankind.'

In some languages the final word in the noun phrase is not always the head. This is the situation in various Australian and Amazonian languages, and in Basque: etxe zaharr-etan (house old-PL.LOC) 'in old houses.'

History

Since bound forms in general derive from free forms, it is not surprising that there is evidence of case markers deriving from nouns and verbs, often via postpositions. For instance, the Hungarian illative ('into') case marker -ba as in világ-ba 'into the world' derives from a noun bél 'innards' and the allative case marker-tharri in the Australian language Kunggari derives from a verb tharri 'to become.'

Case marking may also be lost. This is quite striking in Europe, particularly among the Romance languages. The Latin system of noun inflection illustrated in Table 2 has been lost from the Romance languages except for a reduced system retained in Rumanian. Modern Greek and the Germanic languages too have lost case distinctions over the last two millennia, with English and Afrikaans having lost all case marking on nouns, though German still retains a four-case system: nominative, accusative, genitive, and dative and Modern Greek a three-way system (nominative, accusative and genitive, dative and genitive having merged in the language). In languages like English and the Romance languages case distinctions have been retained on pronouns. Case marking can fall prey to phonetic attrition and the availability of prepositions and word order as alternative means of making the relevant distinctions must also be a factor in the loss of case.

Case-Oriented Research

Abstract

Case-oriented research focuses on interconnections among parts and aspects within single cases. In the case-oriented approach, the researcher attempts to make sense of each case as a singular, interpretable entity. In-depth knowledge of the cases included in a study is usually considered a prerequisite for the examination of patterns observed across cases. Case-oriented researchers often study one case at a time, but they also may study multiple instances of a given phenomenon (e.g., comparable instances of ethnic conflict). The distinctiveness of case-oriented research is apparent when this approach is contrasted with the variable-oriented approach, where researchers focus almost exclusively on cross-case patterns, without first gaining case-based knowledge.

The Goals of Case-Oriented Research

Today, social scientists tend to identify case-oriented research with specific techniques of data collection linked to the observation and analysis of singular cases (e.g., direct observation of individuals at the micro level and archival research on nation-states at the macro level). While generally useful, the identity of case-oriented research with specific techniques of data collection is unfortunate, for it obscures basic differences between case-oriented research and conventional variable-oriented research. More fundamental than differences in methods of data collection is the contrast between goals (Ragin, 1987). Case-oriented strategies are distinctive in that they are centrally concerned with making sense of a relatively small number of cases, selected because they are substantively or theoretically significant in some way (e.g., Eckstein, 1975; Gerring, 2006; Mahoney and Goertz, 2004; George and Bennett, 2005). Conventional variable-oriented strategies, by contrast, are centrally concerned with the problem of assessing the relationship between aspects of cases across a sample of generic 'observations', often with the goal of inferring general patterns that hold for the larger population.

For example, a researcher might use a case-oriented approach in order to study a small number of firms in an in-depth manner. Suppose these firms are all thought to be unusually successful in retaining their best employees while at the same time investing in them and thus enhancing their potential value to competing firms. How do these firms do it? Do they all do it in the same way? Clearly, to answer these questions a researcher would need to conduct an in-depth study of the firms in question, focusing on how they accomplish this outcome. By contrast, a variable-oriented researcher might study the predictors of variation in rates of 'employee retention' across a large sample of firms. Is it more a matter of firm or industry characteristics? Do these two sets of factors interact? Useful answers to these questions would be based on careful analysis of relationships between variables, using data drawn from a survey of a large number of firms – the more firms (and the more varied they are), the better.

As these two examples illustrate, what matters most is the researcher's starting point, and here the issue is very simple: Does the researcher seek to understand specific cases or to document general patterns characterizing a population? This contrast follows a long-standing division in all of science, not just social science. von Wright (1971) argues in *Explanation and Understanding* that there are two main traditions in the history of ideas regarding the conditions an explanation must satisfy in order to be considered scientifically respectable. One tradition he calls 'finalistic' and is anchored in the problem of making facts understandable. The other is called 'causal-mechanistic' and is anchored in the problem of prediction. The contrast between case-oriented and variable-oriented research closely parallels this fundamental division. In the two examples just described, the first researcher uses the case-oriented approach in order to make certain facts understandable – the spectacular success of a handful firms in retaining their most valuable employees; and the second researcher uses the variable-oriented approach in order to derive an equation predicting levels of retention, based on a large sample of firms, and to draw inferences from this analysis to an entire population.

Researchers may select specific cases for in-depth study – seeking to make them 'understandable' – for a variety of different reasons (Stake, 1995; Gerring, 2006; George and Bennett, 2005). For example, cases might be chosen because they are extreme in some way and thus present a process or phenomenon in relatively pure form (e.g., Dumont, 1980). Cases are sometimes selected for in-depth study for the opposite reason – because they are typical or run-of-the-mill (e.g., Becker et al., 1961). Researchers select 'typical' cases to learn more about conventional arrangements and practices. Another justification for studying specific cases in an in-depth manner is because they are historically or culturally significant in some way (e.g., Lipset, 1963). For example, some cases may be pioneers, establishing standards and routines imitated by others (Meyer and Strang, 1993). Cases also may be selected for explicitly theoretical reasons – because they challenge a widely held theory or because they support a widely questioned theory (Eckstein, 1975). Very often case-oriented methods are used because the phenomena that researchers wish to study are too complex, context bound, or context sensitive to be studied in any other way (Yin, 1994). Such phenomena require a more encompassing approach, and the researcher must triangulate different types of evidences using different methods. It is also important to note that to make sense of cases researchers

sometimes must collect evidence relevant to the motives and intentions of actors, which, in turn, mandates the use of intensive methods. In short, whenever there is a compelling reason to make the facts of a case or a small number of related cases 'understandable,' a case-oriented research strategy is essential.

Once the distinction between case-oriented and variable-oriented research is established and their contrasting goals acknowledged, it is clear that the importance of techniques of data collection as bearers of the 'case-oriented versus variable-oriented' distinction fades. For example, it is clear that a researcher using case-oriented methods to study a handful of firms might benefit from conducting surveys of their employees and performing a conventional variable-oriented analysis of these data. The results of the survey would contribute to this researcher's depth of knowledge about the firms in question, just as interviewing their top executives or studying their archives would elicit useful information. Likewise, it is clear that the researcher using variable-oriented methods to predict rates of retention could benefit from interviews of top executives or personnel officers to help interpret results found in the analysis of the predictors of retention. Still, the first researcher would remain focused on the problem of understanding the handful of firms in question, while the second would remain focused on the problem of explaining variation in retention rates across a large number of firms and making inferences from this sample to a population. The important point here is that data collection techniques per se are relatively neutral; what matters most are the researcher's goal and the contrasting research strategies that follow from different goals.

The Logic of Case-Oriented Research

The logic of case-oriented research is fundamentally configurational. Different parts of each case are understood in relation to one another and in terms of the total picture or package that they form together. The organizing idea in such research is that the parts of a case may constitute a coherent whole – that they have an integrity and coherence considered together. For example, researchers who study families often find that patterns of interpersonal accommodation are so enmeshed that a 'dysfunction' cannot be remedied without addressing many different aspects of a family system all at once. Likewise, researchers who study cultures often observe that cultural traits seem to come in packages that defy easy disassembly. The 'parts' that case-oriented researchers examine can be quite varied. In macro-level research, for example, the 'parts' of a case might include institutions, path dependencies, social structures, historical patterns and trends, routine practices, cultural beliefs, singular events, event sequences, connections to other cases, the case's larger environment, and so on. What matters most is that the investigator makes sense of multiple aspects of the case in an encompassing manner, using theory as a guide.

Campbell (1975) offers a rough formalization of this approach in his examination of the logic of case study research. Campbell argues that at first glance the in-depth study of a single case appears to be lacking in scientific merit because there is only one case to explain and many possible explanations to choose from. He notes, however, that case study researchers routinely 'reject' theories because they do not explain the facts of their cases. Furthermore, despite having only one case, they often must struggle to find theories that work. Why is it so difficult? The key to this puzzle is the simple fact that every theory has many implications, relevant both to features of the case in question and to causal processes and sequences operating within the case. Thus, researchers evaluate many theoretical implications relevant to their cases to see if their cases conform to expectations. Not all features of a case may be compatible with an initial theory, and the researcher must either find an alternate theory that works better, revise an existing theory, or propose an entirely new one (Walton, 1992).

Campbell (1975) suggests that each separate theoretical implication can be seen as a different 'observation' for 'testing' a theory. Thus, a single case becomes many observations – some contradicting and some supporting competing theories. Collectively, competing theories and their different implications define all theoretically relevant aspects of the case in question. The researcher's task is to see which theory does the best job of explaining aspects of the case relevant not only to its own implications, but also to the implications of competing theories. Thus, after defining and selecting relevant aspects of the case, the researcher assesses the explanatory power of each theory. The theory (or combination of compatible theories) that best covers both its own implications and those of competing theories prevails and provides the basis for the investigator's representation of the case.

In the end, the researcher crafts an explanation that satisfies as many theoretical implications as possible in a coherent manner. The success of a case study hinges on (1) the number of relevant aspects of the case the researcher can encompass with his or her explanation, (2) the success of the researcher in showing that his or her portrait of the case actually makes sense of all theoretically relevant aspects, and (3) the agreement of other scholars that all relevant aspects of the case in question have in fact been addressed by the researcher in a convincing manner. Of course, the most successful case studies accomplish much more than theoretical and substantive coherence. They also may advance theory or establish important lessons for policy makers (White, 1992). Still, theoretical and substantive coherence should be considered preconditions for these more ambitious goals (Yin, 1994).

Campbell's (1975) argument that case-oriented researchers test multiple theoretical implications for each case underscores the configurational nature of this type of research. Because theoretical implications direct the researcher's attention to 'observations' (i.e., different aspects of a single case) that cannot be independent from one another, the researcher must make sense of them all at once, as a package. Furthermore, because different theories typically have implications of different aspects of the case, the researcher's attention is directed to a broad range of aspects, all of which may be interconnected in some way. Thus, case-oriented researchers must examine overlapping configurations of aspects as they weigh the explanatory power of competing theories.

Case-Oriented Research on Multiple Instances

Case-oriented researchers sometimes conduct a series of case studies, selecting cases strategically so that the knowledge that

these cases generate may accumulate. For example, a specific type of evidence that is not available in one case may prompt the investigator to select for his or her next study a case that offers this evidence. In this manner, case-oriented researchers may develop theoretical arguments in much the same way that psychoanalysts build theory from the analysis of a series of patients, admitting to their practice patients who promise to enhance their thinking and their theories in some way.

This case-by-case, grounded approach can be contrasted with a research strategy that takes *multiple instances* of a phenomenon as its starting point. For example, a researcher might be interested in the formation of green parties in Western Europe and focus on a handful of parallel cases. The key contrast between the study of multiple instances and studying a series of cases is the *timing* of the selection of cases. In serial case studies, findings from one case determine the selection of the next case; in the study of multiple instances, by contrast, the researcher identifies multiple instances of a phenomenon at the outset of the investigation. Of course, the researcher's definition of the set of relevant cases may shift in the course of the research as the investigator learns more about the phenomenon (see Ragin, 1997, 2000). The key point is that the study of multiple instances begins with a preliminary specification of the set of relevant cases.

Generally, when researchers study multiple instances, they focus on a qualitative outcome of some sort, a change that occurred over a specific period of time, signaling some sort of shift or transformation relevant to the case as a whole (e.g., Skocpol, 1992; Morgan and Prasad, 2009; Stryker, 1990; Bloemraad, 2006; Chen and Weir, 2009; Fourcade-Gourinchas and Babb, 2002; Riley, 2005; Steinmetz, 2008; Mahoney, 2010; Swenson, 2002). Accounts and explanations of these qualitative changes typically invoke convergent causal conditions – the specific combination of causally relevant conditions that prompted the change. In many respects, these combinations can be seen as causal recipes (Ragin, 2008) because all the relevant ingredients for change must be in place for it to occur. Specifying a causal recipe entails not only listing the relevant ingredients, but also identifying the processes and mechanisms involved in the production of the outcome (Steel, 2004; Bennett, 2008; George and Bennett, 2005). Even as lists of combined conditions, causal recipes are pregnant with implications about processes and mechanisms (see, e.g., Boswell and Brown, 1999).

Depending on the goals of the study, the specification of a causal recipe for a chosen case may be considered a hypothesis relevant to other cases. In this way, the endpoint of a case study may be a testable hypothesis about other cases, especially when this endpoint is a more or less 'portable' causal recipe linked to a general outcome – a qualitative change experienced by other cases as well. The case is viewed not just as an empirical event but also as a token of a type of empirical phenomenon which is analyzed in order to develop a general hypothesis that explains events of that type.

Consider, for example, a researcher conducting a study of protest against the International Monetary Fund (IMF) in Peru. Through analysis of a variety of case materials – newspaper articles, interviews, secondary sources, published surveys, and so on – the researcher might conclude that these protests occurred because of (1) the severity of austerity measures imposed by the IMF as a condition for the restructuring of Peru's debt repayment, (2) the high concentration of the poor in urban slums, (3) the perception of widespread corruption on the part of government leaders, and (4) the substantial prior level of political mobilization and contention. This explanation of IMF protest cites a specific combination of conditions and has the character of a recipe: all four conditions were met simultaneously in the case of Peru, and together they explain the dramatic turn to protest.

Using the analysis of Peru as a springboard, a researcher could move in either of two directions. The first direction would be to find other instances of protest against IMF-imposed austerity and examine the extent to which these cases agree in displaying the same recipe, the same combination of four causal ingredients found in Peru. Do all (or virtually all) instances of IMF protest display these four antecedent conditions? This strategy employs the common qualitative research strategy of 'selecting on the dependent variable,' an approach that is almost universally, but mistakenly, condemned by quantitative researchers (see, e.g., King et al., 1994; Geddes, 1990; for a defense, see Dion, 1998; Ragin, 2000, 2008). The second direction would be to try to find other instances of Peru's recipe and examine whether these countries also experienced IMF protest. In essence, the researcher would select cases on the basis of their scores on the independent variable. In this example, however, the 'independent variable' is a causal recipe with its four main conditions all satisfied. The goal of the second strategy would be to assess the sufficiency of the recipe: Does it invariably (or at least with substantial consistency) lead to protest?

Both of these strategies are set theoretic in nature and conform to the two general set theoretic approaches described in Ragin and Rihoux (2004) and Ragin (2008). The first is an examination of whether instances of the outcome (protest against IMF-mandated austerity) constitute a subset of instances of a combination of causal conditions (i.e., Peru's recipe). The researcher examines other instances of IMF protest to see if the same combination of four ingredients existed in these other cases. This demonstration would establish that the four causal conditions in question are consistent with an argument of necessity. The second is an examination of whether instances of a specific combination of causal conditions (Peru's recipe) constitute a subset of instances of an outcome (IMF protest). The researcher would identify countries that experienced the same intersection of these four conditions, to see if they exhibited IMF protest as a consequence. This demonstration would establish that the combination of causal conditions is consistent with an argument of sufficiency. Of course, both strategies could be used, and if both subset relations were confirmed, then the two sets (the set of cases with Peru's causal recipe and the set of cases with IMF protest) would coincide. While it might appear that the two strategies together constitute a correlational analysis, it is important to recognize that correlations are strong only if there are many 'null–null' instances – cases that lack both the causal recipe and the outcome. Neither of the two research strategies just described depends on or uses such cases in any direct way. It is also important to understand that from a case-oriented viewpoint, these two tasks – the assessment of sufficiency and the assessment of necessity – are distinct and should not be

Table 1 Case-oriented research: assessing necessity versus sufficiency

	Causal recipe absent	*Causal recipe present*
Outcome present	Cell 1: cases in this cell challenge the argument of necessity but are not directly relevant to the assessment of sufficiency.	Cell 2: cases in this cell may confirm either necessity or sufficiency, depending on the researcher's goals.
Outcome absent	Cell 3: cases in this cell are not directly relevant to the assessment of either necessity or sufficiency.	Cell 4: cases in this cell challenge the argument of sufficiency but are not directly relevant to the assessment of necessity.

conflated, as they are in a conventional variable-oriented analysis based on symmetric measures of association.

Table 1 summarizes the case-oriented approach to assessing the connections between conditions and outcomes. It is important to understand that different ideas about the causal recipe in question motivate different research strategies, especially with regard to case selection. If the researcher suspects that the conditions identified in the recipe are necessary but not sufficient, then the next analytic step is to examine other instances of the outcome (i.e., select on the dependent variable). Specifically, the researcher seeks to establish that instances of the outcome reside in cell 2 of Table 1, with no cases in cell 1. Cases in cell 4 do not challenge the argument of necessity. By contrast, if the researcher suspects that the recipe is sufficient but not necessary, then the next analytic step is to examine other instances of the causal combination. Specifically, the researcher seeks to establish that instances of the causal combination reside in cell 2 of Table 1, with no cases in cell 4. Cases in cell 1 do not challenge the argument of sufficiency.

Of course, it is common for a hypothesis based on one case to be disconfirmed by other cases. For example, suppose that the 'true' recipe for IMF protest has five ingredients, not four, indicating that the researcher overlooked an important ingredient in the case of Peru. The results of the sufficiency analysis of the four-condition recipe would reveal cases in cell 4, which in turn would challenge the argument of sufficiency. The cell 4 cases would have only four of five causal conditions in the 'true' recipe and thus would not exhibit the outcome. Alternatively, suppose that the recipe based on the Peruvian case is needlessly complex and should have only three causal ingredients, not four. The results of a necessity analysis of the four-condition recipe would uncover cases in cell 1.

The key point is that in case-oriented research, the standard 2×2 table of outcome cross-tabulated against cause (which in case-oriented research is usually a causal recipe, not a single independent variable) is disaggregated and partitioned because the different cells of this table have different interpretations and different analytic uses. This approach contrasts sharply with conventional variable-oriented research, where the usual endpoint of the analysis of a 2×2 table (or its interval-level equivalent, a scatterplot) is a global, symmetric measure of association embracing all cases at once. It is also important to emphasize that these symmetric statistics reward researchers for having as many cases as possible in cell 3 (the null–null cell). By contrast, cell 3 plays no direct role in the case-oriented assessment of either the sufficiency or necessity of a causal condition or a combination of causal conditions.

Incongruities Between Case-Oriented and Variable-Oriented Research

Case-oriented research is distinct from variable-oriented research in many ways. The distinctiveness of the case-oriented approach is often overlooked, and researchers using different strategies talk past each other when discussing their methods. While some scholars emphasize philosophical differences between case-oriented and variable-oriented strategies, there are striking and profound differences between the two approaches at the practical level. The practical level refers to the relatively mundane procedures researchers use when working with evidence to produce social scientific representations of what they have learned – that is, summaries of findings and patterns.

The importance of practical differences as a basis for miscommunication between case-oriented and variable-oriented researchers can be seen clearly in the contrasts between two very simple procedures: the search for causal commonalities across multiple instances of an outcome in case-oriented research and the examination of the correlation between two variables across a sample of observation in variable-oriented research. The search for commonalities is usually part of an effort to derive limited generalizations from the in-depth study of a modest number of instances. A researcher might attempt to identify common antecedent conditions for an outcome these cases share. This researcher might argue further that the shared antecedents are necessary conditions for the outcome – that is, if theoretical and substantive knowledge support this interpretation.

Consider the following contrast: a researcher conducting an in-depth study of a select group of firms – those that are able to both invest in and retain their best employees – might identify causally relevant features shared by these firms. Shared features, in turn, might point to a possible formula for success and offer lessons for other firms. The search for commonalities across a select group of cases is the most basic case-oriented strategy applied to multiple instances. By contrast, the examination of a correlation between two variables across a sample of observations in variable-oriented research is usually conducted with the goal of establishing that two conditions or aspects covary. For example, high rates of retention might be correlated with high levels of employee compensation across a sample of firms. This correlation, in turn, might be interpreted causally: the researcher would argue that one reason firms differ in their employee retention rates is that they differ in how well they compensate employees.

While both procedures seem deceptively simple and straightforward, these two ways of producing results from evidence involve sharply contrasting practical orientations toward cases, outcomes, and causal conditions.

Cases

When a researcher using variable-oriented methods computes a correlation between two variables, the relevant cases become more or less invisible and variables take center stage. Furthermore, the set of cases included in the computation must be fixed before the researcher can compute the correlation. Once this set is fixed, usually at the outset of an investigation, it is rarely altered. What matters most is that the cases (which are seen as 'observations') belong to the same general 'population' and that they are drawn from this population with an eye toward randomness or representativeness or some combination of these criteria.

In a case-oriented study of commonalities, by contrast, cases have clear identities and are usually chosen specifically because of their substantive significance or theoretical relevance. Furthermore, the set of relevant cases may shift during the investigation because the researcher may decide that one or more cases do not 'fit' with the others. For example, a researcher studying 'firms that invest in and retain their top employees' might decide that several firms originally thought to belong to this group really do not belong, and that maybe one or more that were thought to be outside this group actually belong in it. This flexibility is maintained throughout the investigation because the core concepts (e.g., 'investing in employees') may be revised as the researcher learns more about relevant instances.

Outcomes

In correlational studies, researchers usually identify a dependent variable – an outcome that varies across cases. Typically, such outcomes are aspects of cases that vary by level, for example, level of satisfaction, level of bureaucratization, and so on. Sometimes the outcome variable is categorical, indicating whether or not some event has occurred (e.g., filing a complaint), and sometimes it is a frequency or a rate (e.g., rate of employee retention). The important point is that the outcome must vary across observations. The goal of the research typically is to explain, if possible, why cases have different values on the dependent variable. Such research is centrally concerned with the question of 'why.' For example, a researcher might seek to explain why some employees are more satisfied than average and others less so, why some firms have higher retention rates than average and others less than average, and so on.

In a case-oriented study of commonalities, by contrast, the outcome is often something that does not vary substantially across the chosen cases. In a study of firms, for example, cases might be chosen precisely because they all display the same outcome – a specific pattern of successful retention. Recall that the goal of a case-oriented study of commonalities is to identify common causal conditions linked to a specific outcome across a relatively small number of purposefully selected cases. Thus, the focus is on cases with a specific outcome, not cases that vary widely in how much they display this outcome. While the outcomes in a study of this type will not be exactly identical across cases, the researcher must demonstrate that the outcomes in the cases selected are in fact enough alike to be treated as instances of the same thing. Finally, unlike correlational studies, which are centrally concerned with the question of 'why' (as in: Why some more than others?), case-oriented studies are centrally concerned with the question of 'how' (as in: How does it happen?). How do firms succeed in retaining their most valuable employees?

Causal Conditions

In a correlational study, causation may be inferred from a pattern of covariation. If a variable thought to represent a cause or to be an indicator of a key causal condition is strongly correlated with the outcome variable, then the researcher may make a causal inference. Usually, the researcher will assess the relative strength of several causal variables at the same time. The typical goal is either to find out which one explains the most variation in the outcome variable or simply to assess the relative importance of the different independent variables. In effect, variables compete with each other to explain variation in the dependent variable. In most investigations, each causal variable is considered sufficient, by itself, for the outcome or an increment in the outcome. That is, each one is considered an 'independent' variable capable of affecting the outcome variable, regardless of the values of other causal variables.

In a case-oriented study of commonalities, by contrast, causation is typically understood conjuncturally. The goal of this type of analysis is to identify the main causal conditions shared by relevant cases. Causal conditions do not compete with each other, as they do in correlational research; often, they combine. How they combine or 'fit together' is something that researchers try to discern using their in-depth knowledge of cases. Because all the cases have more or less the same outcome, the usual reasoning is that the causally relevant conditions shared by cases provide important clues regarding which factors must be present to produce the outcome in question. When constructing this argument, the researcher is especially sensitive to the possibility that a given causal requirement (i.e., a necessary condition) may be met in a variety of different ways.

The study of the commonalities shared by a set of similar instances is not always explicitly concerned with causal conditions. Instead, the commonalities identified by researchers help them deepen their knowledge of the research subject and thus lay the groundwork for the construction of a 'composite portrait' (see Ragin and Amoroso, 2011). The researcher works back and forth between ideas and evidence to refine the portrait (Katz, 1982). While not explicitly causal, procedurally the method is the same: researchers make sense of the 'facts' of their cases by identifying and interpreting commonalities. Case-oriented researchers often shy away from causal statements because they have been warned repeatedly that case studies are not good tools for making causal inference (e.g., Campbell and Stanley, 1966). However, even the construction of composite portraits based on commonalities results in representations of cases that are full of causal implications.

These and other practical differences in how researchers using case-oriented versus variable-oriented methods work with evidence to produce results provide many opportunities

for disjunctures in findings. For example, from the perspective of variable-oriented work, the study of commonalities across a small number of instances is fraught with analytic sins and errors. (1) The number of cases is too small and too nonrandom to warrant any kind of inference (King et al., 1994). (2) The procedure 'selects on the dependent variable' (i.e., focuses on cases with more or less the same value on the outcome variable). This practice may deflate otherwise robust correlations (Collier, 1995; Collier and Mahoney, 1996; King et al., 1994). (3) Researchers may drop cases that 'do not fit' at various stages of the analysis, which seriously undermines any effort to generalize beyond the cases that remain (King et al., 1994). (4) The most important causal factors (i.e., causally relevant commonalities) do not vary and thus are impossible to assess, and so on (Lieberson, 1991, 1994; Goldthorpe, 1991, 1997).

Likewise, from the perspective of case-oriented work, the examination of the correlation between a causal and outcome variable across many cases is fundamentally flawed. (1) Typically, there are so many cases that there is no way for the researcher to know if they are all really comparable and thus belong together in the same analysis. (2) Fixing a population or sample boundary also fixes the assumption of homogeneity, which usually is not warranted. Investigators should be able to redefine the set of relevant cases as they learn more about them (Ragin, 1997). (3) It is difficult to determine how something 'comes about' by comparing cases with different levels of the outcome. The partial instances (i.e., those with lower scores on the outcome variable) are likely to provide many false leads (Lijphart, 1971, 1975; Ragin, 1997). (4) It is pointless to try to isolate the 'independent' effect of any causal condition when several factors usually must combine for a particular outcome to occur (George, 1979), and so on. In short, at a practical level the two approaches seem almost antithetical. It is no wonder that findings diverge and researchers often talk past each other (Rueschemeyer, 1991; Ragin, 1997).

Bridging Case-Oriented and Variable-Oriented Research

While the gulf between case-oriented and variable-oriented research seems great, it is possible to span it. Consider the following scenario: a researcher using case-oriented methods studies several instances of an outcome (e.g., a small number of firms that are very successful in investing in and retaining top employees), documents causally relevant commonalities, and then constructs a general, composite argument about how these firms do it. This argument leads to four specific recommendations (which might be labeled X_1 to X_4) based on the observed commonalities. A second researcher reads the report of this study and decides to evaluate it with a large sample using variable-oriented methods. This researcher collects information on a random sample of firms and finds that independent variables X_1 to X_4 do not distinguish more successful from less successful firms, using various measures of employee retention. In short, the second researcher shows that there is no statistically significant difference in the retention rates for firms with and without these four aspects, considering these aspects one at a time or in an additive, multivariate equation.

What went wrong? Usually, the researcher using variable-oriented methods will claim that the first researcher's 'sample' was 'too small' and 'unrepresentative.' Thus, the identification of X_1 to X_4 took advantage of specific aspects of the selected cases. The first researcher might counterattack by arguing that causally relevant commonalities identified through in-depth study are very difficult to represent as 'variables,' and that the second researcher's crude attempt to operationalize them fell far short. Indeed, the first researcher might argue that it would take in-depth knowledge of each firm included in the variable-oriented study to capture these conditions appropriately and contextually.

These criticisms and countercriticisms are quite common. However, the incongruity between the two hypothetical studies can be resolved without resorting to derogation. The first researcher in this example – the one using case-oriented methods – selected on instances of the outcome and identified four causally relevant conditions shared by the firms in question. In essence, this researcher worked backward from the outcome to causes and thus identified potential necessary conditions for the outcome (Ragin, 2000). Are these conditions truly necessary? In part, this is an empirical question. To gain confidence, the researcher should examine as many instances of the outcome as possible, to see if they agree in displaying these four causally relevant conditions (or their causal equivalents). But it is also a question about existing knowledge. Is the argument that these four conditions are necessary consistent with theoretical and substantive knowledge? Do they make sense as necessary conditions? If the researcher's finding is consistent with existing substantive and theoretical knowledge, then the argument that these four conditions are necessary is strengthened.

How should the second researcher – the one using variable-oriented methods – respond to the argument that these four factors are necessary conditions? At a more abstract level, the specification of necessary conditions is relevant primarily to the identification of cases which are candidates for an outcome. Cases cannot be candidates for an outcome if they do not meet the necessary conditions. But many cases may meet the necessary conditions for an outcome and still not exhibit the outcome because they lack additional conditions which, when combined with the necessary conditions, establish sufficiency for the outcome. In fact, the cases displaying the outcome may be only a small minority of those that meet the necessary conditions. Thus, while there are clear gains from identifying necessary conditions, as in the hypothetical case-oriented study, the identification of causally relevant commonalities shared by instances of an outcome does not establish the conditions that are sufficient for an outcome. Thus, the variable-oriented researcher's finding that these four conditions do not distinguish low-retention firms from high-retention firms across a large sample of firms does not directly challenge the argument that these conditions are necessary.

The variable-oriented analysis of these four conditions across a large sample of firms is much more directly relevant to their sufficiency. To argue that these conditions are jointly sufficient for the outcome, it would be important to show that when these four conditions are combined the outcome follows. In other words, the variable-oriented researcher could evaluate sufficiency by examining the correspondence between the combination of the four causes, on the one hand, and the outcome, on

the other, across a large sample of firms. Still, this analysis would be an evaluation of sufficiency, not necessity, and the results of this analysis would not bear in a direct manner on the claim of necessity made by the case-oriented researcher.

Notice that the resolution of the disjunction described here provides a framework for integrating the two strategies. The results of case-oriented research on shared antecedent conditions may establish potential necessary conditions. Assuming that theoretical and substantive knowledge support the idea that these conditions are necessary, the next task is to verify this, moving from a small number of positive instances of the outcome to many. If the extension of the initial case-oriented results to many cases holds, then the next step is to address the sufficiency of these conditions. Researchers should select instances that display these conditions to see if they agree in displaying the outcome. If they do not, then in-depth study of disconfirming cases should help researchers identify relevant sufficient conditions.

This sketch identifies only one of several ways to integrate case-oriented and variable-oriented inquiries. The general and most important point is that it is possible to integrate these two approaches if researchers are careful to distinguish between necessity and sufficiency and separate the analysis of these two aspects. More generally, this discussion underscores the distinctiveness of case-oriented research, especially the case-oriented study of multiple instances of an outcome.

Abstract

This article discusses the practice of doing case study research at a high level. Rather than attempting a comprehensive overview, the article focuses attention on three critical issues, by: (1) offering a working definition of case studies to determine whether case study research is to be the method of choice in the first place; (2) identifying exemplary case studies that can serve as a way of setting high standards; and (3) suggesting procedures for seeking to make a case study credible and generalizable – two of the most common challenges in strengthening case study research.

Case Study Research: Practicing at a High Level

The present article discusses the practice of doing case study research, including its use in evaluation research. The encyclopedia has other articles on case studies, covering the history, logic, and methods and analysis of case studies, with less directly related articles on "case-oriented research" and "single-case designs" (see cross-references to other articles at end of this text).

From a practice perspective, the article assumes that you may be doing or planning to do case study research, not just wanting to learn about its history or analytic foundations. Moreover, appearance in an encyclopedia implies that an article should have more lasting value than, say, a chapter in an edited book. As a result, this article strives to cover bolder ground – not only emphasizing the practice of doing case study research, but also practicing it at a *high level*.

To practice at a high level and complementing comprehensive guidance already appearing elsewhere (Yin, 2014), the most critical issues include knowing: whether a case study should be the method of choice in the first place; how to set standards for doing high-quality case studies; and what procedures to consider in anticipating the most likely challenges when doing case study research. The article deals with the three issues, by:

1. offering a working definition of case studies and discussing the implications of this definition in knowing whether a case study is to be the method of choice;
2. identifying exemplary if not classic case studies – deliberately representing different academic disciplines and professional fields – as a way of setting high standards for case study research; and
3. suggesting procedures for addressing two of the most common challenges doing case study research – seeking to make a case study credible and to make it generalizable.

Overall, the purpose of the article is to review the critical issues that you – who may be a seasoned or a budding scholar – may encounter in actually doing a case study.

A Working Definition and Its Implications

An initial concern deals with whether you have appropriately identified your method of choice. To stay on track for doing a case study (as opposed to pursuing some other method), you might ask how closely your planned study matches a working definition of case studies – as well as the implications of abiding by such a definition.

The working definition considers a case study to be:

- An empirical inquiry that closely examines a contemporary phenomenon (the *case*) within its *real-world context*.

The resulting case study will be an up-close and in-depth inquiry into a specific, complex, and real-world phenomenon (the *case*).

This working definition befits case study research but also distinguishes it from other social science research methods, such as surveys, experiments, histories, and economic studies. The definition's main implications therefore deserve a bit more of your attention.

First, by following the working definition, have no doubt that the 'up-close' and 'in-depth' aspects imply an intensive data collection effort. The effort can involve *multiple sources of evidence*, because your inquiry is likely to be based on a combination of: direct observations in the field; lengthy interviews with different kinds of informants; and, where relevant, potentially far-reaching access to documents and archives (e.g., media and data files). You even might carry out a quantitative subanalysis about some aspects of the case. In addition, the interviews and documentary sources will not only add depth to your case study but also can cover actions over an extended period of time. With such a range, your completed case study can be more than a mere 'snapshot' of events.

Second, as the main subject of your case study, the 'case' will preferably be a concrete entity (e.g., a person, organization, community, program, policy, practice, decision, or event), existing in a specific time and place. In contrast, when the term 'case' is used in an abstract sense (e.g., an argument, claim, or proposition), its study does not readily point to using the case study method. Rather, most if not all social science methods, and not just case study research, are capable of dealing with arguments, claims, or propositions.

Third, your case study may consist of a single case (a *single-case study*) or contain two or more cases (a *multiple-case study*). Both situations satisfy the working definition. Your decision on whether to include a single or multiple cases will depend on the nature of your case study. For instance, if the case being studied involves a part of the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10507-0

social world rarely accessible to social scientists (e.g., the illicit activities of drug dealers; or the inside relationships among the key executives in a company), a single revelatory case study will be the likely result. Alternatively, if your case study starts with a theoretical proposition that will benefit from a comparison of deliberately contrasting or complementary cases, a multiple-case study will be the likely result.

Fourth, accounting for the *real-world context* assures that a case study will embed a case within an actual setting and circumstance. In this sense, case studies do not isolate their case(s) in some artificial environment (as in conducting an experiment in a laboratory or holding survey interviews over some electronic medium like a phone or a Web site). Covering the contextual conditions adds to a fuller and hopefully more accurate understanding of the case.

At the same time, accounting for the context creates an extra burden on a case study: The case and its context may not necessarily have clear boundaries. For example, a case study of a contemporary organization can lead to a possibly difficult choice: whether a predecessor version of the organization should be considered to be part of the case or part of the context (see **Example 1** for another illustration).

As a final observation, the working definition can accommodate different epistemological orientations in doing your research–typically, a contrast between an *interpretivist* (or *relativist*) orientation and a *realist* orientation (see Schwandt, 2007, for succinct definitions of these terms). The differences in orientations represent deeply felt worldviews and not merely terminological differences (e.g., Yin, forthcoming). To give but an inkling of the worldview differences, from an interpretivist perspective, you might want your case study to acknowledge a world with multiple realities and multiple meanings, with findings that are observer dependent. In doing such a *qualitative case study*, attending to multiple sources of evidence (such as field observations and interviews) can help you to get at these multiple meanings. Alternatively, from a realist perspective, your case study may be examining a reality that is assumed to be observer *in*dependent. An important motive for collecting evidence from multiple sources would then assume a cross-checking objective – to determine the convergence of the evidence.

Exemplary (if not Classic) Case Studies

Besides testing your planned study against the working definition and its implications, you also can check whether you are on the right track in doing a case study by closely examining previously published case studies – preferably ones that have been frequently cited in the research literature. More important, you can use such case studies to set a high standard for your work, hoping that some aspect of your planned case study – its design, data collection, or analysis strategies – resembles the desirable features of one or more of these published case studies.

Making such comparisons is not only possible but also fair, because the published case studies exist in nearly every academic discipline and professional field. Such diversity means that you should readily be able to find case studies in your chosen discipline or field. The brief review that follows will give you a flavor of the kinds of case studies available for your inspection and review.

Early Roots in Sociology, Psychology, and Anthropology

For instance, scholars readily trace some of the earliest case studies to the department of sociology at the University of Chicago (the *Chicago School*). Its members long ago produced case studies with an enduring heritage in the social sciences (e.g., Platt, 1992). To mention but a few of these case studies, they typically focus on different social roles, ranging from *The Polish Peasant in Europe and America* (Thomas and Znaniecki, 5 vols., 1918–20), to *The Hobo* (Anderson, 1923), to juvenile delinquents (Shaw, 1930), and to medical students (Becker et al., 1961).

In addition to the case studies from the Chicago School, other early case studies also examined local communities, with *Middletown* and *Middletown in Transition* perhaps being two of the most well-known and highly regarded (Lynd and Lynd, 1929, 1937). Social groups, such as members of local clubs (e.g., Whyte, 1943/1993) and unemployed men (Liebow, 1967) also have been frequent subjects of case studies. The works by Whyte and Liebow in particular have attained a classic status, coming in part as a result of scholars giving their works an inordinate amount of attention, including inquiries about their methods and leading to an array of supplemental writings (e.g., Whyte, 1984, 1989, 1992). Besides providing a revealing understanding of underappreciated segments of society, both works demonstrate how someone outside of the social group being studied can befriend the group and use participant–observation to conduct a case study. Liebow (1993) later produced yet another variant of case study research, which takes the form of life histories as cases.

At the same time, a different strand of case studies, with equally deep roots, also has existed in the field of psychology. The case studies there are likely to be about clinical patients or about rare occurrences involving individual human behavior (e.g., Rolls, 2005). These kinds of case studies still appear with frequency in clinical psychology. The case studies are likely to appear in separate journal articles, with the most famous neurological case – a person who had lost the ability to record new memories (Corkin, 2013) – having been the topic of over 30 such articles published between 1957 and 1968 alone.

Example 1 Defining the Case in a Case Study

The case being studied is a small group of friends and their interactions and relationships. Whether the friends' parents and siblings are to be considered part of the case being studied or part of the context for the case will affect the nature of the case study's questions and findings. The initial definition of the case should therefore explicitly identify the people considered to be inside or outside of the group, with the consequences explained and justified as part of the case study design – even though such a preliminary bounding of the case can later be revisited.

Finally, a longstanding case study tradition also has existed in the field of cultural anthropology. The anthropological field methods continue to provide a model for doing case study fieldwork, with participant – observation along with questionnaires administered to field participants being a frequent combination of data collection (e.g., Emerson, 2001, pp. 4–7). The earliest anthropological studies tend to emphasize the customs, traditions, and daily life in specific societies or social groups, such as Margaret Mead's classic *Coming of Age in Samoa* (1928), which studied individuals and families in three villages. As with many other older and classic works, although Mead's conclusions have come under later scrutiny, her methods and approach have nevertheless been accorded their due recognition (e.g., Reichardt and Rallis, 1994, p. 7). Although the early anthropological studies may not have dwelled on any particular 'case,' later studies have certainly focused on specific cases, such as the six high schools in Lawrence-Lightfoot's (1983) contrast between public and private schooling.

Contemporary Case Studies

Continuing to the more contemporary scene, one classic case study examined the confrontation between the United States and the then-Soviet Union during the Cuban missile crisis (Allison, 1971; Allison and Zelikow, 1999). The case study has long been a best-selling book in the field of political science. In this case study, and in contrast to those typically based on extensive field observations and interactions, the bulk of the case study's evidence comes from an extensive set of post hoc interviews as well as access to an exhaustive array of documents, some only made available years after the crisis. Another case study, marked by a similar combination of post hoc interviews and access to an exhaustive array of documents, analyzed the decision-making and other actions leading to the tragic loss of the space shuttle *Challenger* (Vaughan, 1996). The findings led to a differing interpretation of the disaster's causes – 'sociology of mistake' – than that offered by the Presidential Commission created to investigate the incident.

Community studies continue to be a frequent topic of other contemporary case studies. A case study can deal with a single community (e.g., Small, 2004), as in the *Middletown* studies. Other case studies can focus on a local community organization, rather than on the community as a whole, as the 'case' to be studied. When such organizations are the subject of study, the typical contemporary case study may include two or more organizations as part of the same multiple-case study. A benefit of this approach is the ability to develop insights into different types of organizations, as in a study of four different types of organizations in each of two urban neighborhoods (Marwell, 2007).

In like manner, the contemporary literature contains other exemplary examples of both single- and multiple-case studies. How to choose between these two variants depends on your research questions as well as on the practical constraints of finding one or more cases. In evaluation research, a common design involves a single-case study with wholistic evaluation questions, such as the effects of reforming a single-school district; however, an integral part of the ensuing case study relies on the results from a quantitative analysis, such as regressions that examine the achievement trends among the district's students (e.g., Supovitz and Taylor, 2005).

In contrast, an evaluation in the field of public health followed a multiple-case study design. The case study examined how and why immunization programs can be successful, with the case study covering 12 cases – four in each of three countries in sub-Saharan Africa (Mookherji and LaFond, 2013). Of the four programs in each country, three were considered positive examples because they had shown improved outcomes, and one was considered a negative example because it had shown no such improvement. A further distinctive feature of this study was that, while the main methods and results were reported in a journal article (Mookherji and LaFond, 2013), the individual case studies were made available through a separate Web site (JSI Research & Training Institute, Inc., http://arise.jsi.com). Such a dual arrangement has become increasingly common and gives readers access to both the main work and the supporting evidence.

A third evaluation example chose the interactions between a teacher and a student with developmental disabilities as the 'case,' studying eight such pairs as cases (Miyahara and Wafer, 2004). The case study systematically varied the teaching strategies used in each of the pairs and applied a replication logic to determine the efficacy of the strategies by assessing the students' performance on a variety of psychometric measures over time.

Finally, the preceding study as well as one by Rivera (2008) shows how good case studies have not been limited to book formats but have appeared as articles in contemporary journals. Rivera's case study (discussed later in this article) comes from the field of foreign affairs and appears in one of the top journals in sociology.

Overall, many of the cited case studies have been among the leaders in their field. Others that have been cited have distinctive features in addition to having been carefully designed and conducted. Because debates over the quality of case studies may be unending, a practical strategy for setting high standards for your work will be to acknowledge if not emulate these previously published case studies.

Two Common Challenges in Doing Case Study Research: Credibility and Generalizability

Two common challenges to the quality of case study research derive from caveats over a case study's credibility and generalizability. A high-level case study needs to address these challenges. Although the caveats cannot be entirely dispelled, they can be reduced by practicing certain methodological procedures. Successfully following these procedures in doing a case study will increase the confidence in a case study's findings as well as in the utility of its findings.

Many people may have developed a strong skepticism about case study research because of an early exposure to a poorly executed case study. Alternatively, inappropriate impressions about case study research may have come from the use of case studies as classroom materials in an academic course. Such *teaching case studies* have been specially prepared to

illustrate a key issue in the course and to stimulate classroom discussion. The teaching case studies exist in virtually every field – both the academic disciplines as well as the professions, such as law, business, public administration, urban planning, social work, public health, and medicine. Unfortunately, the teaching case studies, though appearing under the seemingly same 'case study' moniker as *research case studies*, differ sharply from the research case study that you are trying to conduct.

Teaching case studies have a pedagogical motive. Their texts can be manipulated to create a teachable moment, without regard to the need to present evidence completely or fairly. In contrast, research case studies should satisfy research, not pedagogical motives. Therefore, your case study will need to show explicitly how it has collected and presented its evidence, both completely and fairly. Meeting such a challenge becomes one way of producing a *credible* research case study.

Teaching case studies also may not have to be concerned with developing generalizations – possibly other than pedagogical ones or those related to the course being taught. In contrast, your research case study will be of increasing value the more that its findings have implications beyond the study itself. Meeting this challenge means making generalizations from your case study. On exceptional occasions, a single-case study may be so unique or important that no generalization is desired – for instance, Stake's (2005) *intrinsic* case studies and Lawrence-Lightfoot and Davis's (1997) *portraits*. However, barring an extremely compelling subject matter, you will then have to argue compellingly the value of doing such a case study.

These two topics – producing a credible case study whose findings are generalizable – have become the main challenges in doing case study research at a high level.

Building Credibility

How you deal with credibility may depend on the differences, as discussed at the outset of this article, between the *interpretivist* and *realist* orientations. The relevant evidence may assume different characteristics, and the strategies for dealing with different kinds of evidence may differ.

As a general guide, you may think of three ways of strengthening the credibility of a case study: creating an aura of *trustworthiness*, dealing with concerns over *validity*, and striving for *reliability*. You may attend to these three ways in isolation from each other or in any combination.

Creating Trustworthiness

Especially if you have adopted an *interpretivist* orientation, creating a strong sense of trustworthiness may become the main way of building credibility. The trustworthiness begins by convincing readers that you actually did the fieldwork reported in your case study – that is, being "really and fully present – physically, cognitively, and emotionally – in the scenes of action under study" (Eisenhart, 2006, p.574). Even within the pluralistic, multiple-reality assumptions embedded in an interpretivist perspective, a case study needs to demonstrate that the data and interpretations are accurate *from some point of view* [emphasis added], which also implies reporting about the reflexivity or two-way interplay between the researcher and the events and participants in the field (Eisenhart, 2006, pp. 575–579). Helpful procedures in this process of building trustworthiness include keeping a careful field diary and having well-organized field notes. If nothing else, such procedures will convey an important message – which you are trying to be transparent about your research methods.

In pursuing this transparency, a particular ethical challenge arises in assuring readers that your case study has reported and fairly analyzed *all* the collected data. Such a challenge also exists with other research methods, as in doing experiments, where a constant temptation is to find some procedural excuse to exclude data that might in fact have been contrary to initial expectations. In doing case study research, the conversational nature of field interviews and serendipity of field observations can create a gray area whereby contrary but seemingly casual or even incredulous remarks or observations may be ignored because they were not considered to be part of the 'formal' data collection (Yin, 2011, p. 39). As a partial remedy, you might develop a tool, ahead of time, containing a brief but written decision-making framework, explicitly acknowledging your own rules for reporting or ignoring field information (Newman and Brown, 1996, pp. 101–113). You will then need to know when you might be tempted to "make an exception" and to "counter the temptation with an even stronger admonition regarding the dire consequences of breaking your own rules" (Yin, 2011, p. 39).

Shifting to yet another way of dealing with trustworthiness, engaging in *thick description* has been a hallmark of ethnographic research (Ryle, 1949; Geertz, 1973, 1983). Typically, the highly-detailed accounts enable a reader to appreciate and ultimately derive a deep understanding of the social conditions being studied. However, thick description also can play a role in strengthening the trustworthiness of case study research and therefore deserves your consideration as yet another procedure. By engaging in thick description, you can increase or at least surface your awareness of the filter regarding your potential selectivity biases and your use of preconceived categories (Becker, 1998, p. 85). In other words, such description, portraying the people, events, and actions within their locally meaningful contexts, can help to reveal implicitly-held researcher-centric perspectives. These revelations will add to the transparency and in turn the trustworthiness of a case study.

Dealing with Validity

Worrying about the validity of a study offers a second way of addressing the credibility challenge. The validity concept largely derives from a realist orientation. Any interest, much less concern, over validity may not arise with case studies done with an interpretivist orientation (Yin, forthcoming).

Validity issues especially arise when doing an explanatory (compared to a descriptive) case study. In such a case study, the main explanation tries to cover how and why the studied happenings transpired as they did. The quest in effect implies some kind of causal relationships, while fully acknowledging the complexity of such relationships. In setting forth its main explanation, a case study needs to amass credible data in support of these claimed relationships (see **Example 2**). At the same time, some scholars differ in accepting the relevance of causality as a relevant concept in the social sciences (Yin, forthcoming). For instance, Lincoln and Guba (1985, pp. 150–157) consider the social world to be one of *mutual*

Example 2 Using field observations to explain how and why real-world events occur

Case studies often call for the direct study of social processes in local settings – e.g., the operations inside an organization or school, or the workings of community or neighborhood groups. Doing such fieldwork can include direct field observations about causal processes, with the observations leading to explanations about how and why the real-world events have occurred (e.g., Betts, 2013, p. 255; Erickson, 2012, p. 688; Maxwell, 2004; 2012; Miles and Huberman, 1994, p. 132). The observations even can help to appreciate the complexity of causal relationships as they occur in the real world, such as the potential nonlinear and recursive flows of events and the potential multiplicity of causes, both proximal and distal (e.g., Betts, 2013).

Example 3 Illustrating an explanation and a rival explanation

A case study aims to explain how and why an interorganizational partnership came to operate successfully. The main explanation involves the leadership by the lead partner. The case study also entertains and collects data about a rival explanation – that the prepartnership relationships among several of the organizations, but not the lead partner, established the partnership's central working patterns. The case study then thoroughly compares the evidence supporting the main explanation with that supporting the rival explanation.

simultaneous shaping, where 'everything influences everything else' with 'no directionality,' even though outside observers may label some of the happenings as 'outcomes or effects.' In setting forth its main explanation, a case study needs to amass credible data in support of these claimed relationships (see **Example 2**).

To boost the validity of the findings, a case study needs to examine closely not only its main explanation but also one or more *plausible rival explanations*. These rival explanations are similar to those that sit at the core of the experimental method (Campbell, 2014). In doing experiments, much attention has been given over the years to the identification of methodological rivals posing threats to a study's 'internal validity' (Cook and Campbell, 1979). However, little attention has been given to the types of substantive (or real-world) rivals that represent rival substantive claims and not just methodological rivals. Articulating these real-world rivals (see **Example 3**), and then collecting data to check them out, often can be one of the more stimulating aspects of doing case study research, while simultaneously strengthening a case study's validity. **Exhibit 1** presents a tentative typology of such real-world rivals, also listing a well-known group of methodological rivals.

To address rivals, the analytic procedure calls for comparing the evidence in support of a case study's main explanation with the evidence in support of the plausible rival explanation(s). To make the comparison as fair as possible, you should try aggressively and exhaustively to collect data about the rival(s) – as if trying to prove the potency of the rival(s); then, if finding a lack of such support, you can reject the rival(s) (Patton, 2002, p. 553; Rosenbaum, 2002, pp. 8–10). Assuming that the evidence also strongly supported the main explanation, successful comparisons with plausible rivals will increase confidence in the validity of a case study's findings. As noted in the field of education research (but also applicable to many other related fields), "the use of qualitative methods...can be particularly helpful in ruling out alternative explanations…[and] can enable stronger causal inferences" (Shavelson and Towne, 2002, p. 109).

At the same time, a continuing challenge in doing case study research is to understand how plausible rival explanations are best identified, and how best to judge whether a rival is truly plausible and strong or merely a red herring. Similarly, no benchmarks yet exist for deciding how and whether a rival is to be rejected or accepted, or to remain in an equivocal status. Future research will need to fill these gaps.

Striving for Reliability

A third way of dealing with the credibility challenge consists of strengthening the reliability of a case study. The challenge may arise in doing any kind of case study but in particular, in doing descriptive as well as explanatory case studies. The case study needs to convince readers that data have been collected and analyzed consistently and fairly, and that the case study descriptions represent the claimed reality or the perspective of field informants – but not the analyst's imagination. To be avoided is any reference to a case study as a 'story-telling' activity, or to case study analysts as case study 'writers.' Both references connote a freedom of expression that can go beyond the collected evidence. Even when a case study adopts an interpretivist orientation – for instance, deliberately acknowledging the existence of multiple perspectives or fully appreciating the 'meaning' of what is being studied – these perspectives and meanings also need to be accurately rendered.

To strengthen reliability, the desired case study method will first make the data collection procedure as transparent as possible. An important procedure, using a *case study protocol*, can help to promote the needed transparency. The protocol differs from the conventional survey questionnaire that is directed at an interviewee. Rather, the protocol has a series of questions or topics directed at the case study analyst, along with clues and probes pointing the analyst to the potential measures and sources of evidence. A good protocol covers the entire line of inquiry to be followed in a case study. The preferred line of inquiry has questions and topics that nevertheless leave room for discovery and unexpected field occurrences, as well as for the multiple realities likely to emerge qualitatively from different interviewees.

During actual data collection, the desired method will then include a continual striving to triangulate findings, a procedure that also will boost the reliability of a case study. *Triangulation* occurs when the evidence from several different sources converges on the same finding, increasing the reliability of the finding. The triangulating process also can help to operationalize the concepts in a case study, partially offsetting the common concern over the lack of formal measures in much

Methodological Rivals:

1. The Null Hypothesis (the occurrence is the result of chance circumstances only)
2. Threats to Validity (e.g., history, selection, testing, instability, maturation, instrumentation, regression, experimental mortality, and selection-maturation interaction)
3. Investigator Bias (reactivity in field research; also "experimenter effect")

Real-World Rivals:

1. Direct Rival (alternative events explain the results better)
2. Commingled Rival (other events also help to explain the results)
3. Implementation Rival (the implementation process, not a substantive rationale, explains the results)
4. Rival Theory (an alternative theory explains the results better)
5. Super Rival (a larger force, including the ones being studied, explains the results)
6. Societal Rival (secular trends, not any particular actions, explain the results)

Exhibit 1 Types of rivals.

case study research–and thereby boosting a case study's *construct validity* (Yin, 2014, pp. 46, 47).

The opportunity to triangulate derives from the fact that the typical case study fieldwork should actively embrace multiple sources of evidence. In other words, the fieldwork should deliberately seek to corroborate key findings by searching for multiple sources of evidence. In interpretivist situations, as in accurately rendering an interviewee's unique perspective over or 'meaning' about some matter, no other source of evidence may be relevant. Under this circumstance, you would use a triangulating procedure to prompt the interviewee to express the perspective or meaning on more than one occasion or in more than one way, thereby establishing the interviewee's consistency about the matter.

Still, and as with the situation in examining plausible rival explanations, little attention has been given to the development of a formal process for carrying out the triangulation procedure. For instance, no benchmarks exist to define when triangulation might be considered 'strong' or 'weak' or 'complete' or 'incomplete,' and thus whether an analyst needs to continue pursuing new sources of evidence to strengthen an existing triangulation. Future research will again need to fill this gap.

Generalizing from a Case Study

The supposed difficulty in generalizing from a single-case study – or from a small set of case studies – has long been considered a major shortcoming of case study research. How to go about seeking to make generalizations from case studies will probably remain a longstanding quest.

Making Analytic Generalizations

The desired generalization takes the form of an *analytic generalization*, which consists of a substantive proposition or other principle or set of principles, derived from a case study's findings and then claimed to be applicable to other situations (Yin, 2013, 2014).

The generalizing procedure involves extracting a more abstract level of ideas from a case study's findings and asserting, mainly through careful argument rather than any numeric or statistical calculation, how these ideas might pertain to newer situations other than those in the original study. (Generalizing in this manner may resemble what others have called 'transferability,' with the extent of transferability depending upon "the degree of similarity of the sending and receiving contexts" (Lincoln and Guba, 1985, p. 297).) Thus, the preferred analytic generalization is posed at a conceptual level higher than that of the specific case(s) in a case study (**Exhibit 2** highlights the two levels). Presumably, this higher level was needed to justify the importance of studying the chosen case(s) in the first place. In other words, the substantive proposition may be similar to the one that might have started a case study and that has now, upon completion of the case study, gained empirical support (Small, 2009).

In addition, an analytic generalization should go beyond serving only as a 'working hypothesis' (e.g., Cronbach, 1975) – that is, one in need of further study rather than being ready to be generalized or applied to a new situation. This shortcoming is not easily overcome. However, thoughtfully linking an analytic generalization to the related research literature by identifying conceptual overlaps and gaps will help. Replicating the same findings by conducting a second or third case study – analogous to conducting a second or third experiment to corroborate the findings from an initial experiment – also will help (e.g., Yin, 2014, pp. 57–59). Eventually the ideal analytic generalization may not only extend to situations having other 'like' cases but also "apply to many *different types* of cases" (Bennett, 2004, p. 50) [emphasis added].

Exhibit 2 Making generalization: Two levels.

Example 4 Making analytic generalizations from a single-case study

A classic example of the use of analytic generalizations comes from Graham Allison's well-known single-case study of the Cuban missile crisis, in which the United States and the then-Soviet Union confronted each other in a warlike manner that threatened to spread into a global conflict (Allison, 1971; Allison and Zelikow, 1999). The case study posits three theories to explain the crisis, alternatingly matching the actions predicted by each theory with the actions that actually occurred. The most potent combination of theories then becomes the basis for the analytic generalization and its implications for a broad array of international relationships described by the author – certainly was not limited to the features of the particular 'case' that was studied (i.e., limited to missile crises or even to relationships involving the United States and the Soviet Union).

Example 5 Making analytic generalizations from another single-case study

Another illustration of an analytic generalization appears in a journal article (Rivera, 2008). The case study examines how the Croatian government came to portray the country's past, present, and future in the aftermath of the wars of Yugoslav secession. The wars had left a reputation-damaging effect, threatening Croatia's highly-valued tourist industry. The case study shows how, in response, the government reframed the country's past by omitting the war in its representations of national history, repositioning the country as more closely sharing a history and culture with its Western European neighbors. The explanation for these findings then draws from a theoretical framework, in which the author innovatively extends Erving Goffman's well-regarded sociological work on "stigma and the management of spoiled identity" (Goffman, 1963) from the individual to the institutional realm. The author concludes by claiming that the analytic generalization has applicability to other situations of collective memory and cultural sociology.

'Case Study,' not 'Case'

One major barrier in trying to generalize from case studies may have arisen as a result of confusion between generalizing from a 'case study' and generalizing from a 'case.' Thus, when people question how to generalize from a 'case study,' they may inadvertently think in terms of how to generalize about the 'case(s)' in the case study – typically invoking a sample to population logic, as in making a *statistical generalization*. Such thinking results in an immediate pressure to expand the number of cases. However, you need to remember that the classic case study research may be limited to examining a single case in-depth, and the relevant issue is whether and how to claim a generalization under such a circumstance.

Overcoming the confusion requires understanding that the goal is to generalize from a case study, regardless of the number of cases in the case study. Two other scholars also make the same distinction between a case and a case study. While the case being studied may (or may not) be considered "an instance of a larger class of events" (e.g., George, 1979; George and Bennett, 2004, p. 17), the case study approach involves "the detailed examination of an aspect of a historical episode to develop or test historical explanations that may be generalizable to other events" (George and Bennett, 2004, p. 5). In their terms, the *episode* might be considered the 'case,' and the *historical explanations* the analytic generalizations derived from the case study.

Though not using the same terminology, other prominent works have devoted attention to analytic generalization, also distinguishing it from statistical generalization: (1) Mitchell's (1983) discussion of *logical inference* and *statistical inference*; (2) Bromley's (1986) *case inference* compared with *statistical inference* (pp. 290–291); and (3) Donmoyer's (1990) *schema*. A fourth work, by Burawoy (1991), covers the *extended case method* – his way of describing how a generalization 'extends' a case study to some broader significance (pp. 271–280).

At the same time, no formal procedures yet exist that can guide you in seeking to make analytic generalizations, unlike the ample and almost mechanical guidance available for making statistical generalizations. As a result, you should again appeal to the existing literature for the best examples, while also setting a high standard. To get you started, consider the following two examples. Both deliberately illustrate analytic generalizations on the basis of *single*-case studies (see **Examples 4 and 5**).

Where You Go from Here

This article has defined and discussed the practice of case study research emphasizing the focal topics that will enable you to practice case study research *well*. A major assumption has been that you are in the midst of doing or planning to do your own case study. See if you can: work with an explicit definition of case studies, as presented in the working definition at the outset; cite, use, and relate your case study to some exemplary if not classic case studies; and adopt and use the procedures and tools suggested here and in the literature to meet the challenges of credibility and generalizability. You may not excel the first time. But over a series of case study projects, you should eventually be practicing case study research at a high level.

Case Study: Logic

Anthony M Orum, University of Illinois at Chicago, Chicago, IL, USA; and Loyola University, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The study of single cases, or case study research, has become one of the most important and popular methodological tools at the disposal of social science researchers. This article discusses the general logic of case study research. It provides a basic definition of the case study and then suggests three kinds of case studies – the typical, the prototypical, and the deviant. In addition, it also speaks to the strengths of the case study, as a way of studying history and the evolution of the case, and identifies pitfalls and challenges. Illustrations and examples are furnished throughout.

Introduction

Today there is a renewed interest in qualitative research and in case study research, in particular. Scholars can thank a number of people for sparking this interest, among them, Skocpol (1979) who through a careful and brilliant analysis of social revolutions revealed how researchers can employ a small sample of cases to study broad and significant issues. Case studies have a long and distinguished pedigree in the social sciences, dating from writings like those of Lynd and Lynd (1929) on Middletown, as well as Gans (1962) and Whyte (1943) on neighborhoods. The resurgent interest is not merely based on impressionistic evidence. In just the past several years, new and important writings, such as those by Gerring (2004, 2007) and George and Bennett (2005), have helped to elucidate the logic of case studies, both single cases as well as comparative cases. Moreover, a quick review of the social science citation index will reveal the growing, indeed exploding, number of citations to the works of Gerring (2004, 2007), Ragin (1992), Ragin and Becker, (1992) as well as the present writer and his colleagues (Feagin et al., 1991).

A Definition of the Case Study

While people use case studies for a host of different projects, as, for example, the study of social revolutions, cities, democracies, among other objects, very little careful attention has been given to the definition of a case study itself. This is a major problem. Without a clear definition of a case study, it is hard to know how, if at all, one can generalize to some larger set of cases. Is a particular study a case of a city, or a case of a neighborhood? Is it a case of a person, or of a social role? These and other questions must be answered at the very outset of the project in order for other researchers to know how to properly employ the results of a particular empirical investigation, and this becomes all the more critical as case study research is done more often and in a more diverse set of fields in the social sciences.

Here we shall define a case study as an in-depth study of a single phenomenon whose boundaries and content can be made conceptually and empirically clear. There are two key elements to this definition. One is that the phenomenon has a clear content, and the other is that it also has boundaries within which it can be examined. Thus, one could be interested in social revolutions, as the contents, and the boundaries for such social revolutions can be those of states, or even regions, within which they occur. Very often, in fact, the contents may shade into the definition of the boundaries, as social revolutions begin within states but then spread into regions, e.g., the recent Arab Spring in the Middle East. Equally often the contents themselves may be defined and redefined over time as the particular phenomenon evolves. It may begin with a small network of people but then evolve into a variety of organizations that become, in effect, social movement organizations. Social movements provide perhaps the clearest example of how the contents and boundaries may shift and become vague. Other case studies, like those of neighborhoods, or even of social roles, can furnish instances where the clarity is greater – but conceptual clarity will always require considerable and careful attention in the study of cases.

The Selection of Cases: Types and the Reasons/ Criteria for Selection

Once one identifies and defines the contents and boundaries of a particular case study, the next issue is to think about and decide on the larger population of cases to which one wants to generalize. Will the case, for example, be one that sheds light on the nature of American political parties, or will it be all political parties in general? Does one wish to generalize to all cities, or to all neighborhoods, or only to low-income neighborhoods?

In thinking more deeply about the choice of a particular case and of the larger population to which one wants to generalize, one must carefully decide about the specific nature and character of the case itself. In the past, social science researchers sometimes neglected this issue, but the more that scholars turn to case studies today the more important it becomes. Here we shall suggest three particular types that have found their way into the literature recently. For a more refined definition of cases, the reader is advised to turn the illuminating article by Brenner (2003).

The Typical Case

Generally speaking, most students of case studies, if they are confined to only one or two cases, in particular, choose to think of their case as typical of the larger population to which they

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44002-X

hope to generalize. There are a number of such instances, but perhaps the most famous is found in the pioneering research of Lynd and Lynd (1929). Working in the 1920s and 1930s, well before the methods and costs of social science research had advanced, the Lynds wanted to identify a city whose population was typical of that of the United States. Such a city, they hoped, would allow them to study the nature of work and family life in a setting that represented the average, or standard, setting in which Americans at the time lived. The city they chose was Muncie, Indiana, and the title they gave to their now-famous books was that of *Middletown*. They spent years exploring the city and its past, did interviews with local residents, and created a portrait of everyday Americans and America. They believed that their findings, uncovered during the Depression years of the 1930s, represented the way that urban life in America was experienced. Their work and that of other researchers who following their landmark research, also uncovered in Muncie, Indiana, uncovered such things as the dominance of a single upper-class family and the precarious nature of economic life at the time (see, for example, Caplow et al. 1985).

Muncie, the Lynds argued, provided a typical urban setting, and because it was typical, the Lynds believed they could generalize their research to the nature of American life in general. Note that unlike scholars today, who would draw a random sample of the American population, based on such parameters as age, gender, class, and race, the Lynds contextualized the life experiences they studied. Work was defined by the nature of work in Muncie, religious life was defined by the nature of religious institutions in Muncie, and civic life was defined by the nature of civic life in Muncie. The urban and historical context was essential, they believed, to their research: people were embedded in the daily comings and goings of the place rather than being disconnected as would happen with a typical social survey.

The Prototypical Case

A second type of case that one might choose to select is what can be called a prototypical case. The prototype represents a case that is not merely the average or typical instance of a phenomenon but is one that, in the eyes of the researcher, furnishes a model of how particular phenomenon might develop in the future in a range of cases whose character is similar to that of the prototypical case. The prototype represents a single case, but its full dimensions can be illuminated through comparisons to other instances of the same general population of cases.

One of the most compelling instances of the prototype occurs in de Tocqueville's (1945) analysis of democracy in America. Tocqueville traveled in the United States in the 1830s and succeeded in writing the most masterful portrait ever of the origins of American culture and politics. He cast his analysis as an effort to understand both the causes and consequences of American democracy. He believed that in understanding these conditions his analysis would foreshadow how democracy would eventually emerge in European nations.

Thus he argued that it was the general equality of conditions among Americans, as compared to their European counterparts that helped to promote and sustain the democratic institutions of the United States. America, he argued, did not have a long history of social and political inequality as existed during the course of European feudalism, and thus it was the very cultural foundations here that helped to sustain the effort to promote political equality. In addition, Americans were accustomed to creating and populating various types of voluntary associations, such as clubs and similar organizations, and this too, by comparison with European countries, further helped to sustain the democratic institutions.

By laying out these several and varied preconditions for the emergence of democracy in America, then, Tocqueville hoped to show systematically how the United States differed from such countries as France and England, and therefore, by implication, what the special causes of democracy were. None of this is to suggest, by the way, that he was unaware of the flaws and failures of America in the nineteenth century. He was well aware of the real inequalities that existed, among them in terms of racial differences as well as in terms of the development of capitalism. It was the American ideals, embedded both in the culture and in the institutional makeup that was so especially unique and powerful to the character of the country.

While Tocqueville of course developed his analysis through a continuing, if often implicit, comparison between the United States and European countries, his work was notable for the depth of his analysis and profound insights in the study of America, itself. Like other students of case studies, particularly single cases, he was intent on digging more deeply into the nature of American democracy and comparing it, often implicitly, with other nations he knew well.

The case study as a prototype is a very important method and strategy for case study researchers, and one that should be employed more often as case study research becomes more popular. However, the researcher must remember that this type of case is notable not for its typicality but for its exceptional nature, one that, in the eyes of the researcher, could serve as a model that other similar cases could follow in the future.

The Deviant Case

A third type of case is that of the deviant case study. Here, as in the instance above, the particular case is taken as special, and its analysis proceeds on the assumption that its unique qualities will help to shed light on a broader set of cases and instances in the population. However, unlike the prototypical case, the use of the deviant case is pursued to reveal how the exceptional instance illuminates the broader set of typical or unexceptional cases. One of the most notable examples of the deviant case in the social sciences is the study undertaken of the International Typographers Union (ITU) by Lipset et al. (1956) in the 1950s.

This particular case study chose a question very different from studies of typical cases. Instead of asking what the characteristics of this typical instance are, they wondered how and why the ITU was able to sustain democratic institutions, such as elections and a rotation of leadership, when, in fact, at the time no other unions were able to do so. In other words, how and why was the ITU so special? They presumed, in their research (as Tocqueville did in his), that their findings and insights would enable other unions, if they chose to do so, to introduce democratic institutions and practices as well.

Through an examination of the archives of the union, personal interviews, and election results, Lipset and his colleagues uncovered some important results. Among other things, they found that the members of the ITU tended to be more highly skilled and educated as well as more engaged in union activities than the members of other unions. They reasoned then that these higher levels of skills and active engagement in the workings/politics of the union promoted a greater democracy within it, allowing alternative points of view and working against the continuing domination by a single group of leaders and their cohorts. Although these results only pertained to the case of unions, and their internal politics, it was obvious that they also had a bearing on the nature of politics in other organizations, perhaps even those of nation-states. (Indeed, Lipset et al. suggested that higher levels of skills and greater engagement among the citizens of nation-states also might work to promote more democratic politics in those settings as well.)

Although it has been many decades since this work was completed, this particular case study stands as an important example of how a deviant case – one that displays an atypical pattern – can be extremely useful in highlighting the usual, or typical, conditions for a particular set of institutions. Like Tocqueville's example, that of union democracy takes a case that is an outlier, in effect, and attempts to show it as a model that might be followed by the larger set of cases to which it generalizes.

Case Study Analysis: An Emphasis on Process and Time over Structure

Case study research is celebrated for the depth of its analysis, and, in successful instances, for the range and quality of its insights. While it can be used to confirm, or disconfirm, specific hypotheses, as in the case of the research by Lipset and his colleagues on union democracy, it is often used as a means of generating and developing new ideas. What exactly is it about case study research that allows this to happen? If the difference does not lie in the quality of the researcher – and we assume it does not – what is it about the very nature of the research itself that promotes new insights and ideas?

Research on case studies permits the researcher to study more deeply and extensively the nature of the phenomenon itself, whether a city, a social role, or a political movement. In a word, it enables the researcher to study the process, or the development of the particular phenomenon, over time (George and Bennett, 2005). Let us take an example to show how this can take place. Suppose that a researcher is interested in the consequences of living in a segregated neighborhood as compared to an integrated neighborhood, and chooses to focus only on African–American and white American households, and their relative proportions. Now a standard quantitative study, using a wide number of cases, typically would use some kind of statistical measure of segregation, or integration, as the celebrated studies using the index of dissimilarity do. Here the advantage of the quantitative approach lies in the range of cases that one can bring to bear on the problem.

A researcher who uses case study research has different, but equally significant, options. He can explore the matter of segregation versus integration in another way. Suppose the researcher chooses to study a single neighborhood, one that has changed over time in terms of its racial composition. Here the advantage of case study research lies in the ability of the research to explore the process, or actual history, of segregation and key moments in how it unfolds over time. The researcher may choose to study a neighborhood that was previously populated primarily by blacks – hence was segregated – and that has now become more integrated, populated both by blacks and whites. (Alternatively, as is evident in a great deal of research on segregation, the researcher could choose a neighborhood that once was primarily white, and has now become home to more and more black residents.)

The recent research of Pattillo (2007), a sociologist, examines just such a phenomenon. Pattillo was curious about the process that unfolded as a neighborhood changed from a poor black to mixed income neighborhood that included black families of greater wealth. Sociologists had argued that a mixture of family households of different incomes ultimately would entail many positive consequences for the remaining poor black families themselves, furnishing a wide range of amenities and offering new and important role models for adults and children alike. Pattillo wished to discover whether this expectation was correct. In her 10-year study of the development of the Oakland–Kenwood neighborhood of Chicago she found that the positive scenario envisioned by many sociologists missed many unintended consequences of gentrification. In this particular setting, she uncovered many conflicts and resentments. The poor black families, in particular, came to resent many of the privileges and attitudes of the wealthier black families.

Case study research, moreover, not only permits the researcher to study the process of how a single phenomenon unfolds over time but also has the potential for permitting the researcher to identify the 'tipping point,' – when, for example, a neighborhood changes from a segregated to an integrated one, and the consequences of this transformation. It is not clear if a simple measure of statistical segregation can tap into this kind of shift in the consequences of the shifting composition of the neighborhood, even though one can establish a range of segregation based upon the relative percentages of different racial groups living in an area. However, a case study, with its capacity to furnish a detailed and exacting focus on the changing character of a neighborhood over time, would have precisely this advantage over quantitative studies. It can permit the researcher to focus on the typical outcomes associated with integration, for example, the crime rate among young black males, and then reveal when in a neighborhood's history the 'tipping point' that leads to a lower crime rate is reached – and why. (Conversely, of course, if the researcher is interested in how an integrated neighborhood changes into a segregated black neighborhood, and the consequences that follow, one could study the 'tipping point' when the composition of the neighborhood promotes a higher rate of crime among young black males.)

Finally, let us note that while case studies allow the researcher to examine and explore the dimensions of time and process, the issue of structure always remains available for scholars to study with cases. In the two above examples concerning democracy, the one by Tocqueville emphasizes the role

of history and of time in fashioning American democracy. By contrast, Lipset and his associates focus far more on the ways in which the structural elements of unions, as, for example, the skills and educational level of workers, encourage the development of 'union democracy.'

The Selection of Cases: Some Challenges and Pitfalls

Critics of case study research who typically favor quantitative research in the social sciences almost always raise the issue of the representativeness of case studies, an issue with which one is always concerned in large-scale quantitative studies. Students of case studies can address this criticism in two ways. First, they can do so by noting the special research purposes of case studies, which is to examine a particular phenomenon in depth as compared to the breadth and range of large-scale samples. Second, they can, and must, provide a clear and emphatic rationale for the particular cases they select. Is there something special about a particular neighborhood, for example, which will illustrate some larger concern about low-income neighborhoods? Is there something about a particular state, or set of states, i.e., regions, whose study will further illuminate the nature of social revolutions? The whys and wherefores of case selection, in other words, are of utmost importance to define, and thereby to enable other researchers to effectively use the evidence produced by specific case studies. If there is a frequent flaw in case study research it is that the researcher fails to spell out the whys and wherefores of the choice of cases, making it appear at times as though the choice were simply an arbitrary one. Indeed, if this case is only arbitrary then it is impossible to know whether, or how, the results can be generalized to other cases – even what the population of other cases might represent.

Beyond these two concerns, there is another possible pitfall involved in the selection of cases, and that concerns the way that the researcher chooses the specific cases to examine. Let us consider Skocpol's pathbreaking analysis of social revolutions. She chose to focus on a small handful of successful revolutions in order to illustrate the preconditions of revolution. She examined those revolutions in depth, and to support her claims about why revolutions occurred in one country but not another, she compared the countries with successful revolutions to those where such revolutions were unsuccessful. It was an important and useful strategy. Nevertheless later analyses of social revolutions suggest that had she chosen a larger set of cases, her results might have been different – and not nearly so robust as she claimed (Geddes, 1990).

Skocpol's work also illustrates another pitfall. She chose her cases, of social revolutions in countries, by focusing on the outcomes, on the revolutions, and then making comparisons. Recent work by Collier and Mahoney (1996) suggests that making choices about cases on the outcome, or dependent variable, can be problematic, resulting in what they refer to as 'selection bias.' The following is an example to illustrate how this might work.

Suppose a researcher is interested in whether gentrification is taking place in urban neighborhoods and what the causes of such gentrification might be. The researcher defines the gentrification of a neighborhood in terms of the changes that take place in the material wealth of the neighborhood and, in turn, defines wealth by the average level of family income, the value of residential properties, and the amount of new small commercial business, such as small high-end retail stores, businesses like Starbucks, and the like.

Because the researcher wants to study gentrification and its causes in depth he/she chooses one neighborhood that has gentrified and compares it with one that has not. Now the problem arises because of the level, or degree, of gentrification that can occur in a neighborhood. As in much of social science, outcomes rarely have one single cause, but often multiple ones. If in this instance, the researcher has chosen, let us say, a neighborhood that has become heavily gentrified over time (in terms of the indices noted above), and found the role of developers to be prominent in promoting gentrification, he/she might miss other possible causes, such as the role of real estate agents, or changes in zoning ordinances initiated by the local government, whose role often appears much earlier in the process but furnishes the initial, and critical, push that allows gentrification to occur.

The general point here is this: the selection of cases to study based on the dependent, or outcome, variable can miss possible causes – and also possible consequences – by virtue of its choice of cases. If there is a range of values in the outcome – as in this instance from highly to minimally gentrified – then a selection of only one or even two cases will obviously miss some of this critical variation. The result will be that the analysis will miss other important causes, and even consequences, of the phenomenon in question.

Issues of Theoretical Generalization and Refinement: The Use of Parallel and Different Cases

Because the analysis of a single case can only take the analyst so far, the best rule to follow, if possible, is to examine at least three or four pertinent cases in depth. Multiple cases permit the researcher to refine and develop theoretical arguments, and they do so precisely because case studies permit the researcher to examine cases deeply and, ultimately, to make careful comparisons among those cases.

One example will illustrate the advantages of using several cases and examining them in depth. Orum (1995) was interested in examining various theories about the origins of urban growth. Popular theories had suggested that such growth came about because of special alliances among the leading figures in different major institutional spheres, particularly local government, business, and the media. Orum suggested that such theories were limited only to contemporary circumstances and that they did not help much to explain the sources of growth in the past. Using several different cases and studying them in great depth permitted him to come up with several important discoveries bearing upon issues of urban growth and expansion.

The first case examined was that of Milwaukee, Wisconsin. Tracing its origins back to the early nineteenth century, Orum discovered that the city seemed to go through certain stages in its growth, and that one could not simply rely on explanations of alliances among leaders of different institutional spheres. Thus, based upon intensive study, he argued that, in the earliest

years, the growth of the city relied heavily on local entrepreneurs, people who promoted the city and who, among other things, sold land for it. However, over time this motive force for growth changed, and the main forces turned to new economic institutions, ones that brought in growth by attracting new residents. A third stage happened when the impetus for growth shifted from the local economic enterprises, which had grown somewhat stagnant, to local government. Government sought to expand the community by adding new territory. Among other things, it also became clear in this stage that a single conception of urban growth was inappropriate; growth could take the form of not only new population but also new territory. Such an insight would have been impossible had Orum relied only on the study of this single case in depth. The fourth and final phase happened as the city began to decline. In large part, the decline took place when many of its original industries left for greener pastures in other cities. Under these circumstances, a heavy burden was placed upon local government to devise ways to promote growth, either by expanding its borders or by attracting new industry through various incentives.

In effect, then, Orum's explanation for Milwaukee's growth suggested that such expansion happened by stages, and that at each stage there was a different configuration of local business and political forces responsible for such growth, and that the principal form of growth itself could vary between stages. Next, he asked whether this pattern held only for Milwaukee, or whether it could also describe the trajectory of growth and decline in other parallel industrial cities. Thus, he made comparisons in the pattern and stages of growth in Milwaukee with those in Cleveland, Ohio, a city which, on the face of it, seemed similar in many respects. In fact, the stages and forces of growth at each stage were virtually identical in Cleveland and Milwaukee. He thus argued that among American industrial cities, the nature of growth, and the forces responsible for it, showed important parallels, underscoring his argument on behalf of a stage theory of urban growth.

Finally, Orum pushed the argument one step further, wondering whether the pattern found was only characteristic of industrial growth, and cities, in America. Could the pattern of stages also apply to cities that grew up in the postindustrial era and were themselves postindustrial cities? Here he made a comparison between the patterns in Milwaukee and those in Austin, Texas, a postindustrial city he also had come to know intimately. This comparison showed that the first three stages were very similar in terms of the rapidity of growth, and in the role of entrepreneurs, local business, and local government in promoting such growth in Milwaukee and Austin alike. In the end, then, he refined his overall argument to suggest that the stage view of urban growth in America fit not only industrial-era cities but also cities in the postindustrial era. This suggested that there appeared to be an underlying structural pattern to the growth of American cities, regardless of era. This last comparison also enabled him to draw out differences between Milwaukee and Austin, allowing for further understanding of the nature of urban growth, and difference, in the United States.

In brief, then, as the example of the various cities is intended to illustrate, the careful and systematic study of several cases can permit the researcher both to substantiate important theoretical generalizations and to refine and extend them. Again, this can be done because of the deep acquaintance the researcher gains from the study of cases, an acquaintance unlike that to be obtained with methods like surveys or experiments.

Conclusion: Making the Case for Case Studies

A number of years ago, the author and his colleagues (Feagin et al., 1991) put together a book of essays on how case study research could be done and the advantages of such research. Authors in a variety of sociological fields provided entries on cases in the life cycle, cases of cities, cases of religious institutions, and cases of people who were homeless. At the time, we hoped to help revive a significant methodological tool for the social sciences, one whose use had declined over the course of the twentieth century.

"The times, they are changing," to quote a famous lyric from Bob Dylan. Today case study research is to be found everywhere in the social sciences, although it still faces many of the same standard criticisms it faced years ago. In this article I hope to have made clear that the study of cases is a very powerful and important technique for social scientists. However, one must be ever vigilant about how and why one chooses particular cases, and how to proceed to analyze them. Examples like those mentioned in this article should furnish a start to the nature and logic of case study research. Other recent writings, like those of Gerring (2007), George and Bennett (2005), Chen et al. (2012), and Ragin and Becker (1992) should help to explain and explore these important issues even further.

Abstract

The article reviews case study methods from a historical perspective, starting with the initiative to formalize these methods in the 1970s and examining the distinct contributions to different types of case studies, such as atheoretical or configurative-ideographic cases, heuristic cases, or within-case analysis, among others. It also covers the new developments in case study methods built on the first attempts, particularly its relation to the Philosophy of Science, the elaboration of the concept of typological theory, and the emerging consensus on their comparative advantages and limitations. It concludes by encouraging research collaboration between scholars using diverse methodological approaches.

This article reviews case study methods, also called 'small *n*,' 'comparative,' or 'qualitative' methods. It outlines within-case methods of analysis, including process tracing and congruence testing, and cross-case methods of comparison, including John Stuart Mill's methods of agreement and difference, Alexander George's method of 'structured, focused comparison,' and Charles Ragin's method of 'qualitative comparative analysis.' It argues that case studies can help develop typological theories, or contingent generalizations on the different causal patterns leading to a particular outcome (related notions include configurational analysis and fuzzy logic). This article notes philosophies of science relevant to case study methods, including scientific realism, Bayesian confirmation theory, and Imre Lakatos' methodology of scientific research programs. Finally, it summarizes the comparative advantages of case study methods, including conceptual validity, identification of new variables, and modeling of complex interaction effects, as well as their comparative limitations, including the potential for indeterminacy and the dangers of selection bias. The central conclusion is that the comparative advantages of case study methods, statistical methods, and formal modeling are different and complementary, and that research proceeds more effectively through the combination of these methods than through the use of any one method alone.

Case study methods have been around as long as recorded history, and they presently account for a large proportion of the books and articles in anthropology, biology, economics, history, political science, psychology, sociology, and even the medical sciences. The logic of case study methods, much like that of any historian's or detective's efforts to make inferences from patterns within cases and comparisons between them, is more intuitive than the logic of statistical inference. Until relatively recently, however, the lack of formalization of the logic of case study methods inhibited them achieving their full potential for contributing to the progressive and cumulative development of theories. It is only in the last three decades that scholars have formalized case study methods and linked them to underlying arguments in the philosophy of science. Ironically, statistical methods, though less intuitive, were standardized earlier, so that attempts to formalize case study methods often misappropriated terms and concepts from statistics (McKeown, 1999). More recently, case study methods have evolved from being defined 'negatively,' via contrasts to statistical methods, to being defined 'positively,' by their distinctive logic, techniques, and comparative advantages. This continuing evolution remains a contested process, but there is growing consensus on the proper procedures for carrying out case studies and the strengths and limits of such studies. It is becoming increasingly clear through this process that the comparative advantages of case study and statistical methods are largely complementary and that the two methods can thus achieve far more scientific progress together than either could alone.

The Definition of 'Case' and 'Case Study'

Early efforts to define 'case studies' relied on distinctions between the study of a small versus a large number of instances of a phenomenon. Case studies thus became characterized as 'small *n*' studies, in contrast to 'large *N*' statistical studies. Related to this, one early definition stated that a 'case' is a "phenomenon for which we report and interpret only a single measure on any pertinent variable" (Eckstein, 1975). Case study researchers have increasingly rejected this definition, however, because it wrongly implies, in the language of statistics, that there is an inherent 'degrees of freedom' problem in case studies. In other words, this definition of case studies suggests that with a greater number of variables than observations on the dependent variable, case studies provided no basis for causal inference. In the view of case study researchers, however, each case includes a potentially large number of observations on intervening variables and qualitative measures of different aspects of the dependent variable, so there is not just a 'single measure' of the variables or an inherent degrees of freedom problem. This point is increasingly recognized by researchers from the statistical tradition (King et al., 1994; Bennett and Elman, 2004, 2006).

In addition, the 'small *n*/large *N*' distinction implies that large *N* methods are always preferable whenever sufficient data are available. As argued below, however, case studies can serve useful theory-building purposes, such as the inductive generation of new hypotheses, even when instances of a phenomenon are sufficiently numerous to allow the application of statistical methods.

For present purposes, then, *a case is defined as an instance of a class of events* (George, 1979a,b). The term 'class of events' refers here to a phenomenon of scientific interest, such as revolutions, types of governmental regime, kinds of economic system, or personality types. A case study is thus a well-defined aspect of a historical happening that the investigator selects for analysis, rather than a historical happening itself. The Cuban Missile Crisis, for example, is a historical instance of many different classes of events: cases of deterrence, coercive diplomacy, crisis management, and so on. In deciding which class of events to study and which theories to use, the researcher decides what data from the Cuban Missile Crisis are relevant to their case study of it. Of course, even if one accepts the present definition of a case, there is still room in the context of particular studies to debate such questions as: 'what is this event a case of' and "given this phenomenon, is this event a case of it?" (Ragin and Becker, 1992).

There is potential for confusion among the terms 'comparative methods,' 'case study methods,' and 'qualitative methods.' In one view the comparative method, or the use of comparisons among a small number of cases, is distinct from the case study method, which in this view involves the internal examination of single cases (*see* Comparative Studies: Method and Design). For the present purposes, however, case study methods are defined to include both within-case analysis of single cases and comparisons between or among a small number of cases. This is not an effort to claim wider meaning for the term 'case studies,' but an outgrowth of the growing consensus that the strongest means of drawing inferences from case studies is the use of a *combination* of within-case analysis and cross-case comparisons within a single study or research program, although single case studies can also play a role in theory development. As for the term 'qualitative methods,' this is sometimes used to encompass both case studies carried out with a positivist view of the philosophy of science and those implemented with a postmodern or interpretive view. This present article hews to the traditional terminology in focusing on 'case studies' as that subset of qualitative methods that has adopted a largely positivist framework.

The Historical Development of Case Study Methods

Case study methods have developed through several phases over the last three decades. Prior to the 1970s, 'case studies' consisted primarily of historical studies of particular events, countries, or phenomena, with little effort to cumulate results or progressively develop theories (Verba, 1967). Throughout the 1970s, however, scholars who were dissatisfied with the state of case study methods, and encouraged by the example of the formalization of statistical methods, began to formalize case study methods.

First, Adam Przeworski and Henry Teune (1970) clarified the logic of 'most similar' and 'least similar' case comparisons. In the former comparison, which draws on the logic of John Stuart Mill's method of difference and mimics the experimental method, the researcher compares two cases that are similar in all but one independent variable and that differ in the outcome variable. Such a comparison may be consistent with the inference that the difference in the single independent variable that varies between the cases accounts for the difference in the dependent variable (although for a variety of reasons discussed below, this inference may be spurious). In a comparison of least similar cases, which draws on Mill's method of agreement, the researcher compares two cases that differ in all but one independent variable that have the same value on the dependent variable. If, for example, we find that teenagers are 'difficult' in both tribal societies and industrialized societies, we might be tempted to infer that it is the nature of teenagers rather than the nature of society that accounts for the difficulty of teenagers.

Arend Lijphart (1971) and Harry Eckstein (1975) contributed further to the formalization of case study methods by clarifying the differences among various types of case study research designs and theory-building goals. These authors identified similar types, although their terminology differs, and Lijphart adds an important type, the 'deviant case,' for which Eckstein does not make explicit provision. Their types of case studies correspond as shown in **Table 1**.

The atheoretical or configurative-ideographic case study takes the form of a detailed narrative or 'story' presented in the form of a chronicle that purports to illuminate how an event came about. Such a narrative is highly specific and makes no explicit use of theory or theory-related variables. Most case studies, however, do have an explanatory purpose. These studies generally fall into the category of 'disciplined-configurative' or 'interpretive' case studies, in which general propositions are used, often implicitly, to explain specific historical cases. Another variant of such case studies is the use of cases as examples that illustrate a theory.

Heuristic case studies seek to generate new hypotheses inductively from the study of particular cases. Notably, statistical methods lack this capacity for inductively generating hypotheses, and they typically rely instead on hypotheses derived deductively or borrowed from case study research. An especially important type of case study for developing new hypotheses is the 'deviant' case study. This is the study of a case whose outcome is not predicted or explained adequately by existing theories. Unless the outcome of a deviant case turns out to be a consequence of measurement error, the case is likely to be useful for identifying variables that have been left out of existing theories. Finally, researchers can use case studies to test whether the outcomes and processes that theories predict in particular cases are in fact evident.

Eckstein's and Lijphart's contributions demonstrated that there was not just a single type of case study, but many kinds of case study research designs and many different theory-building purposes that they could serve. Their treatments differed,

Table 1 Types of case studies

Lijphart	*Eckstein*
Atheoretical	Configurative-ideographic
Interpretative	Disciplined configurative
Hypothesis generating	Heuristic
Deviant	?
Theory-confirming/infirming	Crucial, most likely, least likely

however, in that Lijphart relied greatly on statistical concepts and language. He was thus skeptical of the value of single case studies for building social science theories, and, consistent with the widespread preference at the time for 'large *N*' over 'small *n*' methods, he urged researchers to consider several means of either decreasing the number of variables in their models or increasing the number of cases to be studied in order to make use of statistical rather than case study methods. This advice, however, raised the risk "conceptual stretching" (Sartori, 1970), or of lumping together dissimilar cases under the same definitions. Possibly for this reason, Lijphart later placed greater emphasis instead on the controlled comparison of most similar to cases as a basis for causal inference (Lijphart, 1975; Collier, 1993).

Eckstein, in contrast, focused on the use of case studies for theory testing and argued that even single case studies could provide tests that might strongly support or impugn theories. In so doing, Eckstein developed the idea of a 'crucial case,' or a case that "*must closely fit* a theory if one is to have confidence in the theory's validity, or, conversely, *must not fit* equally well any rule contrary to that proposed" (Eckstein, 1975; his emphasis). Eckstein argued that true crucial cases are rare, so he pointed to the alternative of 'most likely' and 'least likely' cases. A most likely case is one that is almost certain to fit a theory if the theory is true for any cases at all. The failure of a theory to explain a most likely case greatly undermines our confidence in the theory. A least likely case, conversely, is a tough test for a theory because it is a case in which the theory makes only a weak prediction. A theory's ability to explain a least likely case is strong evidence in favor of the theory. In this way, Eckstein argued, even single case studies could greatly increase or decrease our confidence in a theory or require that we alter its scope conditions.

Alexander George (1979a,b) further developed case study methods by refining 'within-case' analysis and cross-case comparisons in ways that help each method compensate for the limits of the other. George argued, as Mill himself had, that the 'method of difference' and the corresponding practice of comparison of most similar cases could lead to spurious inferences. One reason for this is that no two nonexperimental cases achieve the ideal of being similar in *all* respects but one independent variable and the outcome. Thus, there is always the danger that left-out variables or residual differences in the values of the independent variables account for the difference in the outcomes of similar cases of (*see* Human-Environment Interactions: Case Studies). In addition, as Mill recognized, phenomena might be characterized by what general systems theorists have termed 'equifinality,' or the condition in which the same outcome can arise through different causal pathways or combinations of variables. Thus, there might be no single necessary or sufficient variable for a phenomenon: it might be that either ABC or DEF causes Y, and that none of the variables A–F is itself sufficient to cause Y. In such circumstances, pair-wise comparisons of cases might wrongly reject variables that contribute to the outcome of interest in conjunction with some contexts but not with others, and might also accept as causal variables that are in fact spurious.

To compensate for these limits of controlled comparison, George developed the 'within-case' methods of 'congruence testing' and 'process tracing' as means of checking on whether inferences arrived at through case comparisons were spurious. In congruence testing, the researcher checks whether the prediction a theory makes in a case, in view of the values of the case's independent variables, is congruent with the actual outcome in the case. In process tracing, the researcher examines whether the causal process a theory hypothesizes in a case is in fact evident in the sequence and values of the intervening variables in that case. Thus, process tracing might be used to test whether the residual differences between two similar cases were causal or spurious in producing a difference in these cases' outcomes. Process tracing can perform a heuristic function as well, generating new variables or hypotheses on the basis of sequences of events observed inductively in cases.

George (1979a,b) also systematized case study procedures by developing what he called the method of 'structured focused comparison.' In this method, the researcher systematically: (1) specifies the research problem and the class of events to be studied; (2) defines the independent, dependent, and intervening variables of the relevant theories; (3) selects the cases to be studied and compared; (4) decides how best to characterize variance in the independent and dependent variables; and (5) formulates a detailed set of standard questions to be applied to each case. In addition, consistent with his emphasis on equifinality, George argued that case studies could be especially useful in developing what he called 'typological theories,' or contingent generalizations on "*the variety of different causal patterns* that can occur for the phenomena in question … [and] *the conditions under which each distinctive type of causal patterns occurs*" (George, 1979a; his emphasis). He thus advocated a kind of 'building block' approach to the development of theories in which each case, while rendered in terms of theoretical variables, might prove to be a distinctive causal pathway to the outcome of interest.

In the 1980s and 1990s, thousands of books and articles made use of these improvements in case study methods in a wide variety of social science research programs. Meanwhile, scholars continued to elaborate case study methods and articulate the ways in which they differed from statistical methods. David Collier, reviewing the development of case study and comparative methods, argued that these methods have advantages in defining and measuring qualitative variables in conceptually valid ways and forestalling the problem of conceptual stretching (Collier, 1993). Charles Ragin argued that qualitative methods were also better than statistical methods at accounting for equifinality and complex interaction effects. Although statistical methods can model several kinds of interaction effects, Ragin noted, they can do so only at the cost of requiring a larger sample size, and models of nonlinear interactions rapidly become complex and difficult to interpret. Ragin also introduced the method of Qualitative Comparative Analysis (QCA), which uses Boolean algebra to reduce a series of comparisons of cases to the minimum number of logical statements or hypotheses that entail the results of all the cases compared (Ragin, 1987). This method, he argues, makes comparisons among cases in ways that treat them inherently as configurations of variables and that allow for the possibility of equifinality and complex interactions. Both Collier and Ragin also noted the limitations of case study methods, including the potential for indeterminacy when attempting to sort out rival explanations in a small number of cases, the difficulty of

attaining a detailed understanding of more than a few cases, and the inability to make broad generalizations on the basis of small numbers of cases.

New Developments in Case Study Methods

Thousands of applications of case study methods in the last two decades have provided fertile ground for further methodological refinements. Three recent key developments include the strengthening of linkages between case study methods and the philosophy of science, the elaboration of the concept of typological theories, and the emergence of elements of consensus on the comparative advantages and limitations of case study methods.

Case Studies and the Philosophy of Science

With regard to the philosophy of science, the 'scientific realist' school of thought has emphasized that causal mechanisms, or independent stable factors that link causes to effects under certain conditions, are important to causal explanation (Little, 1998). This has resonated with case study researchers' use of process tracing to uncover evidence of causal mechanisms at work. It has also provided a philosophical counterpoint to attempts by researchers from the statistical tradition to place 'causal effects,' or the expected difference in outcomes brought about by the change in a single independent variable, at the center of causal explanation (King et al., 1994). Case study researchers have argued that both causal mechanisms, which are more easily addressed by case studies, and causal effects, which are best assessed through statistical means, are essential to the development of causal theories and causal explanations (George and Bennett, 2001).

Another relevant development in the philosophy of science has been the resurgence of interest in Bayesian logic, or the logic of using new data to update prior confidence levels assigned to hypotheses. Bayesian logic differs from that of most statistics, which eschew reliance on prior probabilities. Eckstein's crucial, most likely, and least likely case study designs implicitly use a Bayesian logic, assigning prior probabilities to the likelihood of particular outcomes (McKeown, 1999). One new development here is the refinement of Eckstein's approach, taking into consideration the likelihood of an outcome not just in view of one theory, but in the presence of alternative hypotheses. If a case is 'most likely' for a theory, and if the alternative hypotheses make the same prediction, then the theory will be strongly impugned if the prediction does not prove true. The failure of the theory cannot be blamed on the influence of the variables highlighted by the alternative hypotheses. Conversely, if a theory makes only a weak prediction in a 'least likely' case, the alternative hypotheses make a different prediction, but if the first theory's prediction proves true, this is the strongest possible evidence in favor of the theory (Van Evera, 1997). This helps address the central problem of a Bayesian approach – that of assigning and justifying prior probabilities – even if it does not fully resolve it.

The continuing development of the logic of hypothesis testing has also been relevant to case study methods (*see* Hypothesis Testing: Methodology and Limitations). On this topic, Imre Lakatos argued that a theory can be considered progressive only if it predicts and later corroborates 'new facts,' or novel empirical content not anticipated by other theories (Lakatos, 1976). This criterion helps provide a standard for judging whether process tracing, the designation of new subtypes, and the proposal of new theories from heuristic case studies are being done in a progressive or regressive way. It also provides a philosophical basis for arguing that a hypothesis can be derived from one set of observations within a case and then to some extent tested against the 'new facts' or previously unexamined or unexpected data that it predicts within that same case, although independent corroboration in other cases is usually advisable as well (Collier, 1993).

Typological Theories and 'Fuzzy Logic'

A second recent development in case study methods has been the elaboration of the concept of typological theory. Typological theories occupy a middle ground between covering laws, or highly general abstract propositions, and causal mechanisms. Typological theories identify recurring conjunctions of mechanisms and provide hypotheses on the pathways through which they produce effects. Thus, like QCA, typological theories treat cases as configurations. Unlike QCA, they do not attempt to reduce the number of theoretical statements about the variables, but retain a diverse and admittedly complex set of contingent generalizations, with potentially one generalization per type. Consequently, typological theories are well suited to modeling equifinality.

To construct typological theories, researchers first specify the variables and use them to define the typological space, or the set of all mathematically possible combinations of the variables (this is sometimes termed a truth table in the philosophy of science). At first this may seem to produce an unmanageably large number of combinations: a model with five dichotomous variables, for example, would have 32 possible types. However, once the researcher begins to categorize extant cases in a preliminary way into particular types, it often becomes possible to narrow the range of cases of interest for study. Many types may remain empty, with no extant cases. Some types may be overdetermined for the outcome of interest, and hence not worthy of study unless they have an unexpected outcome. From among the cases and types that remain, the researcher can use the preliminary categorization of cases within the typological space to help identify most likely, least likely, most similar, least similar, and crucial cases for study. Cases in the typological space with unexpected outcomes, or deviant cases, can help identify new causal pathways that can be added to the existing theory in a kind of "building block" approach (George and Bennett, 2001). A related development concerns the concept of "fuzzy logic" (Ragin, 2000). Fuzzy logic treats cases as configurations but rather than using dichotomous or trichotomous variables and categorizations of cases, it allows the use of scaling to give a score on the extent to which a case fits into a certain type. In other respects, the use of fuzzy logic proceeds in ways much like those of typological theories.

The Emerging Consensus on the Strengths and Limits of Case Study Methods

A third development is that while several debates on case study methods continue, others have moved toward synthesis or even

closure, and the overall picture is of an emerging consensus on the advantages limitations of case study methods. As noted above, researchers from a variety of methodological traditions have recognized that because case studies can include many observations, they do not suffer from an inherent degrees of freedom problem. At the same time, it is also widely agreed that particular case studies may suffer from indeterminacy, or an inability to exclude all but one explanation on the basis of available process tracing evidence (Njolstad, 1990). When this occurs, it may still be possible to narrow the number of plausible explanations, and it is also important to indicate as clearly as possible the extent to which the remaining hypotheses appear to be complementary, competing, and incommensurate in explaining the case.

Second, most case study researchers have readily acknowledged the limits of Mill's methods. Ragin's alternative of qualitative comparative analysis makes less restrictive assumptions, but its results are highly sensitive to changes in the measurement or coding of a single case (Goldthorpe, 1997). There has thus been a movement toward typological theories and fuzzy logic, which make still less restrictive assumptions than QCA and are not so sensitive to the results of a single case. In addition, there is growing consensus that the use of within-case methods of analysis helps provide a check on the potential spuriousness of cross-case comparisons (Collier, 1993; Mahoney, 1999; George and Bennett, 2001). Case study researchers consequently seldom if ever rely on case comparisons alone.

Third, there is growing recognition that the case selection criteria necessary for statistical studies are in some respects inappropriate for case studies. Random selection in a case study research design, for example, can result in worse biases than intentional selection (King et al., 1994). There is also increasing understanding that, consistent with the reliance of some case study designs on a Bayesian logic, case studies are sometimes intentionally selected not to be representative of some wide population but to provide the strongest possible inferences on particular theories (McKeown, 1999). There is still disagreement between those who warn against any selection on the dependent variable (King et al., 1994) and who argue that selection on the dependent variable is appropriate for some research objectives (Collier and Mahoney, 1996; Ragin, 2000; George and Bennett, 2001). Related to this is a continuing disagreement over whether single case studies can make only limited contributions to theory building (King et al., 1994), or whether single case studies have indeed reshaped entire research programs (Rogowski, 1995). There is wider agreement, however, that selection bias is potentially more severe in case studies than statistical studies because biased selection of case studies can overstate as well as understate the relationship between the independent and dependent variables (Collier and Mahoney, 1996).

On the whole discussions of these issues have moved toward an emerging consensus on the comparative advantages and limitations of case study methods (Bennett, 2004). These methods' advantages include the conceptualization, operationalization, and measurement of qualitative variables (conceptual validity), the avoidance of conceptual stretching, the heuristic identification of new variables and hypotheses (often through study of deviant cases), the assessment of whether statistical generalizations offer plausible or spurious explanations of individual cases, the incorporation of equifinality and complex interactions effects, and the inferences made possible by combining within-case and cross-case analyses (Collier, 1993; Munck, 1998; George and Bennett, 2001). It is possible that new statistical methods may be able to improve upon the statistical treatment of equifinality and interaction effects, and at least narrow the gap in the treatment of this issue, but the other comparative advantages of case study methods appear to be inherent in their differences from statistical methods.

The limits of case study methods include their inappropriateness for judging the relative frequency or representativeness of cases, their weakness at performing partial correlations and establishing causal effects or causal weight, the necessarily narrow and contingent nature of their generalizations, and the danger that selection bias can be more catastrophic than in statistical studies (Collier, 1993; King et al., 1994; Munck, 1998; George and Bennett, 2001). Fortunately, these are precisely the strengths of statistical studies.

Future Directions in Case Study Methods

Just as the formalization of case study methods in the 1970s inspired a generation of more sophisticated research, the recent further refinements in these methods are likely to lead to still greater sophistication in their use in the social, biological, and even physical sciences. The increasingly evident complementarity of case study and statistical methods is likely to lead toward more collaborative work by scholars using various methods. The recent interest among rational choice theorists in using case studies to test their theories, for example, is an important step in this direction (Bates et al., 1998). Because case studies, statistical methods, and formal modeling are all increasingly sophisticated, however, it is becoming less likely that a single researcher can be adept at more than one set of methods while also attaining a cutting-edge theoretical and empirical knowledge of their field. Collaboration might therefore take the form of several researchers working together using different methods, or of researchers more self-consciously building on the findings generated by those using different methods. In either form, effective collaboration requires that even as they become expert in one methodological approach, scholars must also become conversant with alternative approaches, aware of their strengths and limits, and capable of an informed reading of their substantive results.

Cash Transfers

Abstract

Social protection programming in general, and cash transfers in particular, have been one of the successes of international development's 'war on poverty' since the 1990s. This article discusses the evidence base on the contribution of cash transfer programming to human capital development, economic growth, humanitarian protection, and social norm change. It also considers program governance modalities and challenges. The final section discusses the future direction of cash transfer programming.

Introduction

Social protection programming in general, and cash transfers (CTs) in particular, have been claimed as one of the development successes since the 1990s. Originally pioneered in Brazil and Mexico in the mid-1990s, CTs, which give money to target populations either conditionally (CCTs) or unconditionally (UCTs), have been shown to have significant effects in reducing household income poverty, improving human capital outcomes, and contributing to declining levels of inequality. Buttressed by robust evaluation evidence, CTs have now spread throughout the developing world and are reaching more than 750 million people in middle- and low-income countries (Arnold et al., 2011).

Distinct from safety nets, social protection can take a variety of forms, ranging from public works programs to social transfers and social insurance; but they all aim to act as a buffer against transitory and/or chronic poverty. CTs are one of the most widely favored social protection instruments, as they have proved to be effective in enhancing and smoothing household consumption and increasing uptake of basic services at scale across a wide range of developing countries. More recently, in the context of global financial crises and in light of discussions around international development goals post-2015, social protection is increasingly seen as essential – not only to tackle rising levels of risk and vulnerability, but also to promote social justice and social inclusion (**Figure 1**).

The growing popularity of CTs is partly due to their fungible nature, empowering beneficiaries to spend according to their priorities. However, CCTs, in particular, have gained political acceptability as they are usually contingent on beneficiary families accessing basic services – for example, sending their children to school and attending health clinics. Evidence is still mixed, however, as to how important the conditional aspect of such programs is, and whether positive effects are more related to general household economic strengthening (Baird et al., 2011). Because of this, and informed by

Figure 1 Cash transfer programs in Latin America, Africa, and Asia. Countries shaded in blue were implementing CTs as of 2012; countries with an orange circle began programs between 2009 and 2012. Only programs reaching more than 5000 people were included. Source: Global Savings and Social Protection Database, 2012 as cited in Sridharan, V., 2012. Enhancing the Impact of Cash Transfers: The Latest Trends toward Savings-Linked Social Protection. http://newamerica.net/sites/newamerica.net/files/policydocs/Trends0709.pdf.

commitments to a rights-based approach, a growing number of programs are unconditional. However, as there have been very few methodologically robust comparative evaluations, the research community remains undecided as to the relative merits of CCTs versus UCTs. (One of the few exceptions is the World Bank–funded CT experiment in Malawi in 2010–11, which included a conditional and an unconditional strand. The program aimed to improve girls' school attendance and sexual and reproductive health (see, for example, Baird et al., 2011).)

This article first discusses the evidence base on the contribution of CTs to human capital development (especially nutrition, health, and education), economic empowerment and growth, humanitarian protection, and social norm change. After looking at program governance modalities and challenges, considerations for the future direction of CT programming are offered.

Human Capital Development

Improving the uptake of basic services, especially among children, is one of the core features of most CTs, as the aim is to reduce child poverty and, by investing in the development of children's human capital, to reduce the risk of life course and intergenerational poverty transfers. Here, we briefly review the evidence on how CTs have contributed to improved access and outcomes in three key areas: nutrition, health, and education.

Nutrition

CTs have been shown to improve food consumption, particularly in the poorest countries. In Kenya, for example, participant households were found to consume greater quantities and more diverse foods – with the government reporting a 15% increase in the frequency of consumption of five food groups (meat, fish, milk, sugar, and fats) (Aston and Jones, 2012). Similarly, in Malawi, dietary diversity increased by nearly 25% for households receiving a CT (Audsley et al., 2010); in Ethiopia, beneficiaries of the government's Productive Safety Net Programme (PSNP) were significantly more likely to consume the required 1800 calories per day than non-beneficiaries. However, despite impacts on consumption, the final impact of CTs on measurable outcomes such as stunting and anemia is somewhat mixed – due to the difficulty in establishing the interplay between cash and other inputs such as clean water, sanitation, and health care (Fiszbein and Schady, 2009; **Figures 2** and **3**).

Dietary improvements are partly due to the fact that CTs allow households to purchase food directly. In Malawi, for example, 75% of transfers were spent on groceries (Arnold et al., 2011). While this is higher than the average of 50% found for most CTs, one synthesis study across sub-Saharan Africa found that in six of the seven programs reviewed, the cash was primarily spent on food (Adato and Bassett, 2008). CTs also contribute to dietary improvements by enabling landholding rural households to purchase livestock and other inputs required to boost agricultural productivity and better feed themselves. In Zambia, for example, participants in a pilot CT spent over one-fifth of their CT on livestock (Garcia and Moore, 2012), and in Ethiopia, PSNP participation has been found to increase livestock ownership by 7% (Gilligan et al., 2009).

While CTs increase household food consumption, better nutrition-related outcomes do not always follow. Indeed, Manley et al. (2013), in their analysis of 17 CT programs, found no significant impacts on children's height for age – a key indicator of child malnutrition. Similarly, in Kenya, despite better diets, Ward et al. (2010) found no impact on anthropometric indicators. Other studies have found positive impacts though. For example, in Nicaragua, Hoddinott and Bassett (2009) concluded that the Red de Protección Social CCT had extremely robust impacts on preschooler height, with children

in beneficiary communities 5.3% less likely to be stunted. Similarly, CTs have been associated with significant declines in global acute malnutrition in countries ranging from Myanmar to Niger (Bailey and Hedlund, 2012).

While the specific program components that lead to better outcomes are as yet unclear, evidence suggests that the better diets facilitated by CTs are more likely to translate into better nutritional outcomes when the cash is paired with complementary programming that targets other known deficits (Bailey and Hedlund, 2012; Hoddinott and Bassett, 2009). For example, given that the first 2 years of a child's life are critical to healthy growth and development, messaging directed at infant feeding practices is often key. Instructional components directed at hygiene and sanitation are also important to combat parasites and diarrheal illness. Finally, given that infant nutrition is intimately linked to maternal nutrition, the provision of nutritional supplements to pregnant and breast-feeding women can also have long-term impacts on health; supplements have reduced intrauterine growth retardation by nearly one-third (Hoddinott and Bassett, 2009).

Health

Not surprisingly, since many programs condition benefits on the uptake of certain health care services, CTs have improved uptake rates, particularly among the most disadvantaged communities, who are least likely to utilize such services (Fiszbein and Schady, 2009). However, impacts on health outcomes have been inconsistent (Fiszbein and Schady, 2009). Not only do services vary significantly in their quality, with obvious impacts on outcomes, but also the constellation of influences on health outcomes makes it challenging to isolate impacts – or even impact channels (Fiszbein and Schady, 2009). That said, given some strong successes, CTs have recently been expanded beyond their initial child health mandate and are now targeting diverse outcomes, including safe motherhood and HIV prevention.

An analysis of 13 CT programs, most of them in Latin America, found clear impacts on the use of preventative services such as immunization (Ranganathan and Lagarde, 2012). Long-term impacts are less clear, however. Rasella et al. (2013) found that Brazil's Bolsa Familia has reduced the under-5 mortality rate – in part, through its impacts on poverty-related causes such as malnutrition and diarrhea. Similarly, Ghana's Livelihood Empowerment Against Poverty program has been found to reduce morbidity among older children (Handa et al., 2013), while a small-scale, community-implemented CCT in Tanzania reduced illness rates among preschoolers by more than 10% (Evans et al., 2014).

A key finding on the impact of CTs on health outcomes is the importance of targeting – with the poorest groups experiencing the strongest impacts. UNICEF (2010), for example, found that the highest returns on investment in child health are in rural areas, where fertility rates tend to be higher, preventable child deaths are more common, and health care coverage is low. The importance of targeting was echoed by Manley et al. (2013) in their analysis of child nutrition outcomes, and by Barnham (2013), who found that Mexico's Oportunidades program achieved the greatest declines in infant mortality among groups with high rates of illiteracy and mortality.

The focus of some CCTs has been extended to safe motherhood, given poor progress in reaching the Millennium Development Goal 5 (reducing maternal mortality). Mexico's Oportunidades, and the Philippines' 4Ps (Pantawid Pamilyang Pilipino Program), now have elements promoting safe motherhood. Others, such as Nepal's Safe Delivery Incentive Programme and India's Janani Suraksha Yojana, focus entirely on safe motherhood, paying pregnant women if they attend prenatal clinics and are delivered by a skilled attendant. In their recent review of the effects of demand-side financing on maternity care, Murray et al. (2014) conclude that while the evidence is still slim, CTs can help improve uptake of maternal health services. In El Salvador, for example, Comunidades Solidarias Rurales has had robust effects on rates of institutional delivery (de Brauw and Peterman, 2011).

However, a cautionary note is required. While CTs can improve access to health care, better outcomes also depend on the availability of good-quality health services (Fiszbein and Schady, 2009). Murray et al. (2014) observe that CTs and other demand-side financing schemes do not necessarily lead to higher quality services, and can in fact reduce quality by increasing utilization rates, putting additional strain on already stretched systems. This means that supply-side investments are crucial in order to capitalize on the effects of CTs (Ranganathan and Lagarde, 2012).

The newest application of CTs to health-related outcomes – and one, which highlights the complex decision-making process that produces good health programming – is HIV prevention. An analysis of program impacts identified two pathways for CTs to reduce HIV risk: upstream, by reducing poverty and improving education; and downstream, by directly rewarding healthy behaviors (Pettifor et al., 2013). Though few studies have tracked HIV incidence due to concerns about ethics, the evidence overall suggests that both uptake of education services and sexual behaviors – particularly for girls and women – are malleable.

Upstream impacts are clearly potent. For example, Kenya's CT for orphans and other vulnerable children – which is unconditional and pays caregivers, not adolescents, $20 a month – found that beneficiaries had significantly reduced odds of sexual debut (35% for girls and 18% for boys) compared with their nonbeneficiary peers (Handa et al., 2014). Similarly, Malawi's Zomba CCT, which targeted school attendance, found that beneficiary girls were 60% less likely to become infected with HIV – primarily because participation reduced the odds of transactional sex (Baird et al., 2012). Girls who were enrolled in school had fewer older partners and less sex.

While downstream effects are more rarely measured, there is some evidence that direct conditioning may also work. For example, in Tanzania, a CT that offered payments of either $10 or $20 every quarter if tests for sexually transmitted infections came back negative, reduced the odds of disease after 1 year at the $20 level (de Walque et al., 2012). However, the lack of negative results at 4 and 8 months may mean that it takes time for participants to trust the conditioning – or to extricate themselves from complicated sexual relationships.

The complicated nature of personal decision-making is highlighted by Kohler and Thornton (2012) in their evaluation of an HIV-targeted CCT in Malawi. The program randomly

offered participants financial incentives at the end of 1 year, if they maintained their HIV status. Ironically, while the reward changed neither self-reported behavior nor serology results, men who received a reward were then more likely to engage in risky sex than men who had not received a reward. Women, on the other hand, were less likely to do so.

Education

As with health, CTs have proved to be critical for stimulating demand for basic education services. CT programs targeting education may be either conditional (i.e., children must attend school in order to receive the CT) or quasiconditional (whereby attendance is not necessarily monitored, but communities and households are strongly encouraged to use the cash to invest in children's schooling, as in Ghana and Kenya) (Jones et al., 2013). Global findings suggest that the impact on educational attendance and reduced absenteeism, often stemming from domestic and paid work pressures, is consistently significant (Fiszbein and Schady, 2009; **Figure 4**).

Although schooling is free in many of the low- and middle-income country contexts where CT programs have been rolled out, a range of other costs (e.g., uniforms, books, snacks) make continued access to school challenging, with inability to meet these costs a major cause of dropout for children from poor households. By contrast, the ability to purchase such items due to the CT is associated with confidence, self-esteem, and a sense of belonging to a peer group.

Evidence also suggests that dropping out of school can lead to involvement in more exploitative and dangerous activities, such as transactional sex or sex work, child labor, stealing, or begging (Jones et al., 2013). Similarly, in some contexts, CTs may prevent girls being withdrawn from school and forced into early marriage (Jones et al., 2013).

There is also evidence of some indirect spill-over effects, which reinforce the more direct and positive inputs from schools. Because of a combination of increased awareness about the importance of schooling and the availability of more cash (which, among other things, reduced men's need to migrate for economic reasons), greater parental involvement in children's education has been reported. For example, Jones et al. (2008) found that fathers enrolled in Peru's Juntos Program were becoming more involved in their children's education (benefiting from awareness-raising and parenting classes) and were supporting children's learning at home.

Despite these positive effects, however, there is also a risk that poverty and social class may undermine social relations and play a potentially divisive role in educational settings. Children from beneficiary families in Gaza and the West Bank, for example, reported feeling excluded, because being identified as poor led to discrimination from their peers and, in some cases, teachers (Pereznieto et al., 2014).

Furthermore, while increasing household income can be critical in terms of promoting enrollment and helping to prevent dropouts, the CT amount is often inadequate to improve educational attainment (Fiszbein and Schady, 2009). Part of the problem lies with the resource and capacity limitations of the home environment, but supply-side constraints, i.e., the quality of education provided, are also key. Concerns about the quality of teaching, teacher absenteeism, school-based violence, and limited or poor-quality school psychosocial counseling services are all issues that have emerged in studies on child-sensitive social protection, and which potentially undermine the positive dividends of CTs in education (e.g., Jones et al., 2008; Pereznieto et al., 2014).

Economic Growth

Propoor CTs are also linked to broader economic growth (FAO, 2014; Barrientos, 2012). While it has traditionally been assumed that CTs are a long-term investment, with benefits expected to accrue to the broader economy through improved health and education outcomes for today's children, evidence suggests that CTs also have immediate positive effects on economic growth. These are primarily through increases in

Figure 4 Impact of CCTs on primary and secondary enrollment. Source: Arnold, C., Conway, T., Greenslade, M., 2011. Cash Transfers Literature Review. Department for International Development, Policy Division, London.

beneficiary household consumption, which have follow-on impacts on local economies, and strengthening of recipient asset portfolios, which facilitates self-employment. However, CTs may also affect growth at the highest levels – insofar as they help build a more secure state, they encourage growth, since security is essential to local, national, and international economic investment (Samson, 2009).

Evidence suggests that even small CT programs can stimulate local demand, as poor households gain more purchasing power, which can, in turn, stabilize prices by incentivizing farmers, making trade more competitive. For instance, Malawi's Mchinji CT pilot, targeted at the labor-constrained ultra-poor, averaged only $14 a month but increased spending significantly on food and nonfood items. In an evaluation of the program's impact on economic growth, Miller (2011) found that beneficiaries were important customers for local businesses and were especially important for smoothing sales during the rainy season. The Food and Agriculture Organization of the United Nations (2014), in its evaluation of the impacts of numerous CT programs on growth in sub-Saharan Africa, notes that this consumption helps spread – and multiply – impact, as local businesses are primarily owned by noneligible households. Indeed, models suggest that multiplier effects can be as high as 2.5, though complementary interventions may be required to maximize these (Miller, 2011).

CTs also stimulate economic growth by helping poor households acquire productive assets that enable them to build more secure futures. As the FAO (2014) notes, self-employment is often the exit route from poverty. Even small transfers, if regular, can help poor households manage risk and invest in production. For example, Miller (2011) reports that in Malawi, $14 a month allowed households to increase livestock holdings and agricultural production. Similarly, the FAO (2014) notes that CTs in Zambia, Malawi, and Kenya increased household investment in agricultural assets and inputs; qualitative research in Ghana, Kenya, and Zimbabwe found that CTs increased investment in economic activities – with female-headed households benefiting most in some cases.

Larger transfers may offer households even greater opportunities for investment. In Kenya, for example, Haushofer and Shapiro (2013) report that an unconditional CT, experimental in its design, randomly offered households a one-off grant of either $300 or $1100; beneficiaries increased their livestock holdings by over 50% and their income from self-employment by nearly 40%. Similarly, in Uganda, where the government distributed unconditional CTs of $380 (on average) to more than 5000 young people for enterprise development – worth about a year's average income – Blattman et al. (2013) found that recipients invested most of the cash in training and business assets. Four years later, recipients were 65% more likely to have a skilled trade and had real earnings nearly 50% higher than nonbeneficiaries. Interestingly, impacts were highly gendered; women's incomes raised approximately 2.5 times as much as men's (84% vs 31%) (Blattman et al., 2013).

Barrientos (2012) notes that in order to maximize growth impacts, the design of CT programs is crucial. Transfers must be regular and reliable, and last long enough to rebuild livelihoods. They should also be large enough, as noted above, to encourage investment rather than merely smoothing daily consumption. Eligibility conditions should not encourage asset depletion, which ultimately makes it far more challenging for households to exit poverty. Instead, CTs should be paired with complementary programs that facilitate asset accumulation.

Humanitarian Protection

CTs have a broad set of applications in humanitarian contexts. They have been successfully used in short-term situations ranging from environmental disasters, such as the 2010 floods in Pakistan and the 2011 drought in Somalia, to the reintegration of refugees and former combatants in Burundi and Liberia. They are also addressing longer-term fragility in places such as the occupied Palestinian territories (oPt). While in-kind support (in the form of food, medical supplies, etc.) remains central in some cases and important in many others, experience increasingly demonstrates the appropriateness and efficacy of CTs – even in disaster and fragile contexts (Bailey and Hedlund, 2012).

CTs, whether conditional or unconditional, offer numerous advantages over more traditional forms of humanitarian aid. They can, for example, be planned and implemented far more quickly than other forms of support (Global Humanitarian Assistance, 2012; Carpenter et al., 2012). Metz et al. (2012) report that in South Sudan, while food distributions were only punctual half of the time and were often delayed for over a month, cash payments were typically on time or very close to being so. Similarly, after the floods in Pakistan, the government was able to promptly issue prepaid Visa cards, worth over $200 each, to millions of households (European Commission, 2013). Given the severe damage to infrastructure, in-kind aid would undoubtedly have taken far longer to reach recipients.

Cash can be a more efficient form of distribution. In Jordan and Syria, for example, refugees are able to access their cash benefits via local bank ATMs, which saves the time and expense of creating new distribution systems (Harvey and Bailey, 2011). In Somalia, cash was transferred through local traders and money transfer companies; aid agencies worked closely with local vendors to ensure that food supplies would be available in normal markets and to prevent inflation (Hedlund et al., 2013).

Given gains in efficiency, CTs can be a cost-effective response to emergency situations. In Ecuador, where the World Food Programme offered assistance to Colombian refugees in 2011, CTs were found to be the least expensive way of delivering aid. The marginal cost of direct food distribution was nearly 4 times higher ($11.50 vs $3.03, with food vouchers costing $3.30) (Hidrobo et al., 2012). Metz et al. (2012) concluded that direct food aid was less cost-effective than CTs in South Sudan as well.

CTs allow for a greater level of flexibility than most other forms of aid. That flexibility can be vital for programs and households alike, allowing a more targeted response that protects local livelihoods while also providing a safety net. For instance, after the 2009 earthquake in Indonesia, Oxfam found that while people's livelihoods had not been disrupted, the need to find shelter was precluding adequate participation in income-generating activities. Cash was seen as the best way to help families meet their immediate needs so that they could

resume productive activities to ensure their longer-term survival (Harvey and Bailey, 2011). Similarly, in Kenya, a voucher program not only improved refugee diets, but also strengthened and expanded local markets, positively impacting other people's livelihoods (Harvey and Bailey, 2011).

CTs offer greater flexibility for households too, allowing each to prioritize spending based on their specific needs. While food and shelter are clear priorities, education is also important for families with school-age children. In Southern and Central Somalia, UNICEF's CT reunified families – improving children's school performance as a result – and saved money by reducing demand for expensive institutional care. The flexibility to pay school and medical fees, as well as pay down debt, was also judged crucial by Somali recipients (Hedlund et al., 2013).

While CTs have immediate protective benefits in humanitarian contexts, there is also evidence that they can segue into long-term preventive and promotive programs for vulnerable populations. In Ethiopia, for example, the PSNP, which provides cash (and food) to food-insecure households in exchange for labor on community projects, grew out of decades of emergency food aid that was having no lasting impact on household resilience. Similarly, programs in Kenya that were started by nongovernment organizations (NGOs) in response to high food prices are seeking to influence larger social protection debates (Mohanty, 2010).

This is not to argue that CTs are a panacea for humanitarian protection. Indeed, they share many of the weaknesses of more traditional aid programs – weaknesses that are often driven by the need for urgency in humanitarian contexts. For example, after the 2010 election violence in Liberia, a program offering cash for work or an unconditional grant to adolescents to keep them out of trouble was implemented without respect to national law. Work was offered to children aged 15 and above, despite the law prohibiting employment of children under 16 (Thompson, 2012). Similarly, postdisaster responses all too often suffer from limited coordination. With many agencies working in multiple ways in limited areas, it can be difficult to monitor impacts and draw conclusions. Where the need is great and coordination is limited, such as after the 2010 floods in Pakistan and the 2004 tsunami, establishing what worked and what did not can remain unclear for many years.

Effective targeting and communication can be especially urgent but fraught with difficulty in fragile situations, in which most people are vulnerable and aid is limited. In these contexts, careful targeting is vital, as is clear communication, so that communities understand how benefits are assigned – something that seems particularly rare in humanitarian situations. In Yemen and the oPT, for example, CT recipients often report that they have no idea where their cash comes from, or why they receive it and others do not (Jones et al., 2013). Similarly, in Sierra Leone, the social safety net, far from improving relationships between communities and the state, engendered considerable mistrust (Osofisan, 2011).

CTs, like other aid programming, need to pay careful attention to exclusion and bias on the basis of gender or ethnicity. Oxfam GB and Concern Worldwide (2011), reviewing the gendered impacts of three crisis-oriented CTs (in Kenya, Zimbabwe, and Indonesia), found that while programs can improve intrahousehold relations where women are the targeted beneficiary, overall, CTs reinforced women's traditional roles. Beneficiaries reported that not only did staff emphasize women's responsibility for children – but that they also highlighted men's irresponsibility, marginalizing men's role as fathers.

Social Norm Change

Over time, CTs may also facilitate a shift in constraining social norms. For example, they may empower women to make decisions and handle money, encourage men to spend more time caring for their children, and discourage early marriage. While it takes time to change underlying beliefs about what people ought to do – i.e. injunctive norms – there is increasing evidence that CTs are already changing the descriptive norms that govern people's actions.

In the case of Peru's Juntos program, for example, Jones et al. (2008) found that the program has had some impacts on gender norms. It is enabling women's decision-making and changing local understanding about women's mobility and community participation. There is also evidence that the program is reducing domestic violence and encouraging men to assume greater household responsibility (Jones et al., 2008; see also Hidrobo and Fernald, 2013). Even small steps are likely to have multiplier effects over time, particularly as children witness their mothers assuming productive as well as reproductive roles, and becoming more confident in their ability to contribute to the household economy. Similar results have been reported in Brazil, where women report greater latitude in decision-making, including on contraception.

While evidence is mixed, CTs may also be playing a role in ending harmful practices such as child marriage. In Ethiopia, for example, a program that offered families livestock in exchange for delaying their daughters' marriage was found to prevent marriages of the youngest girls; rates for girls aged 10–14 fell by 90%, though the rate for older girls increased (Erulkar and Muthengi, 2009). There is also evidence that programs in India designed to encourage girls' education and discourage early marriage have been successful at keeping girls in school. Nanda et al. (2014) report that beneficiary girls are nearly 25% more likely to be enrolled in school after the age of 15. Though final evaluations are still in progress, given that education offers girls some protection from early marriage, it seems likely that the overall effects are positive.

However, observed changes in social norms have tended to be small and confined to specific subgroups of CT participants, for several reasons. First, because CTs typically target women as beneficiaries, they often unintentionally reinforce traditional gender roles by relying on women's unpaid work and time to ensure fulfillment of conditions or to attend program-related awareness-raising sessions (Holmes and Jones, 2013; Oxfam GB and Concern Worldwide, 2011). Second, there is some evidence that as programming expands women's horizons, men respond by holding on more tightly to traditional roles. For example, Camacho and Rodriguez (2012) found that not only did Colombia's Familias en Acción program fail to empower women on five measured dimensions, but also that after enrollment, women beneficiaries had a lower probability of being the sole decision-maker about children's education.

They speculate that when school attendance became a condition for receiving the transfer, men took control. Similarly, there is also evidence that (at least in the short term) CTs can worsen domestic violence. Hidrobo and Fernald (2013), for example, found that for Ecuadorian women with less than sixth grade education, CT participation tended to increase emotional violence if their level of education was higher than their partner's.

Cash alone is rarely sufficient to alter deeply held beliefs or change age-old traditions. In India, even where CT participation has increased girls' schooling, there is little evidence that participation – or education – has fundamentally altered their self-efficacy (Nanda et al., 2014). Similarly, in Bangladesh, where the female secondary school stipend has contributed to rising enrollment rates for girls (who are now more likely than boys to attend school), two-thirds of girls still marry before their 18th birthday (UNICEF, 2011).

Program Governance Modalities and Challenges

For the chronically poor and most vulnerable, who are least likely to benefit from economic growth, politics and political change are often the only channels through which they can challenge poverty. National governments' institutional capacity to implement large-scale, poverty-targeted CT programs is therefore key, as are program accountability mechanisms and existing state–citizen relations.

Unfortunately, social protection schemes, including CTs, are often located within comparatively weak ministries, with limited financial resources and high levels of donor dependence. This is especially the case in low-income contexts in sub-Saharan Africa. In a study on CTs in Kenya, Mozambique, Palestine, Uganda, and Yemen, Jones et al. (2013) also found an important disconnect between central and local levels in terms of the rationale for program reforms and procedures. This is often due to weak information flows and human resource capacity deficits at subnational level, with too few (and inadequately trained) program staff to deal with the multiple vulnerabilities facing beneficiaries. For instance, in Gaza, social workers were responsible for managing up to 800 beneficiary cases; in Kenya, community-level work was done entirely by volunteers, and in Mozambique, by poorly trained and remunerated facilitators. Moreover, staffs are not always competent to deal effectively and sensitively with specific vulnerabilities faced by people with disabilities, children, or older people, for example.

Because of the cross-sectoral nature of social protection, it is also difficult to establish effective coordination mechanisms across government, development partners, and NGOs. Single registry databases are beginning to tackle this, recording all information about registered beneficiaries and their program entitlements in order to reduce duplication of effort and promote synergies. In Palestine, for example, following the Brazilian and Chilean models, a computerized single registry database is gradually being made available to all relevant ministries and is expected to significantly strengthen program coordination.

Another critical approach aimed at improving coordination among program designers, implementers, and beneficiaries is to embed accountability mechanisms within CT programs, creating spaces for interaction and information exchange between staff and beneficiaries. Current CTs vary considerably in this respect. In Mozambique, permanentes (local volunteers who take on a program liaison role) and neighborhood committees are important links between beneficiaries and program staff; however, respondents also highlighted that they often serve as gatekeepers. In Uganda, program implementers are trying to engage with local leaders who organize regular community meetings, as well as interacting with beneficiaries on payment days (Jones et al., 2013). Program design has gone a step further in Kenya, where since 2011, community-level committees have been channeling citizen inputs into program decision-making and monitoring (Jones et al., 2013).

Many programs have grievance mechanisms for beneficiaries and nonbeneficiaries, but Jones et al. (2013) found that implementation appears to be weak, partly because in sub-Saharan Africa, CTs are largely seen as a gift – either from political leaders or God – leading to a general reluctance to complain. In other instances, the grievance process was simply too tardy to inspire confidence, or people were concerned about reprisals (Jones et al., 2013).

Finally, delivering regular and predictable social protection support can buttress a 'social contract' – a reciprocal relationship between citizens and their government. In countries where there is relatively good information provision, and where community leaders and local program implementers have not been excessively politicized (e.g., Brazil and Uganda), CTs appear to have consolidated citizen–state ties. However, where programs have been politicized at the local level and are plagued by irregular payments or corruption (e.g., Mozambique and Yemen), confidence in the state has generally not improved, and has even been further undermined. In the oPT, while the Palestinian National Cash Transfer Programme is recognized as a critical coping strategy, there is little awareness of the Palestinian Authority's contribution, even though it funds approximately half of the budget. Many beneficiaries regard the support as being from 'Europeans,' effectively undermining the political mileage that could be gained to help strengthen state–citizen relations.

Future Directions

CTs have undoubtedly contributed to poverty and vulnerability reduction at scale in middle- and low-income countries alike. Long-established programs such as Brazil's Bolsa Familia, Mexico's Oportunidades, and South Africa's Child Grant have achieved meaningful and sustained improvements in the lives of millions of program beneficiaries and continue to protect families from on-going risks and stresses. However, there is still much to do to ensure that programs facilitate a more sustainable exit from poverty and multidimensional vulnerability. Priorities include the need to pay greater attention during program design and implementation to the intersection between social exclusion and poverty (e.g., through developing more gender- or disability-sensitive programs); the importance of developing more embedded monitoring and evaluation systems that draw on qualitative and participatory approaches alongside quantitative methods so as to more effectively tailor programs in the context of profound resource shortages; and the imperative of forging

stronger linkages to complementary services and programs (e.g., vocational training, psychosocial counseling, and microcredit) that can help tackle the multidimensional nature of poverty and vulnerability. Here programs such as Chile's Chile Solidario, which provides families not only with regular cash supplements but equally importantly also with tailored support overseen by a dedicated social worker to help households tackle challenges they jointly identify (e.g., domestic violence, drug addiction, lack of marketable skills, inadequate housing) offers an innovative approach toward which more narrow CT program models could aspire.

Abstract

The career of caste as an anthropological concept provides a fascinating terrain on which to examine how anthropological objects come to be invented and stabilized, and the relation they bear to patterns of sociality, needs of government, and production of knowledge. Many textbooks in sociology and social anthropology represent caste as a fundamental institution of Indian society. In this view, castes are ranked in a hierarchical order and are governed by rules of endogamy, commensality, and purity–pollution that put strict limits on exchange of women and food between castes. The hierarchical order, however, permits the flow of women from lower to higher castes through marriage and the flow of food from higher to lower castes. The caste system is seen to correspond to a rough division of labor, although it is recognized that certain occupations such as agriculture cut across different castes. This textbook picture of the caste system, although influential, has come under serious scrutiny in recent years as being not only ahistorical but also ignoring the power–knowledge axis in the production of social science concepts.

Caste as the Ideology of Indian Society

Louis Dumont's (1980) *Homo Hierarchicus* has long been regarded as an outstanding contribution to the understanding of caste. Dumont argued that principles of hierarchy and holism were central for explaining the caste system. The principle of hierarchy in India, he proposed, was based upon the religious opposition between pure and impure – pollution incurred in the biological processes of life and death was removed in India not through processes of reciprocity (I bury your dead – you bury mine) but through principles of hierarchy. The task of removal of pollution was assigned to the lower castes who became permanently imbued with it. Thus, the separation between castes as well as their hierarchical ordering could be derived from the opposition between pure and impure. The scheme had the simplicity and elegance to make the bewildering diversity of Indian civilization immediately knowable, especially to Western readers.

Dumont's characterization of Indian society has been challenged on the ground that what he saw as a timeless ideology was itself a result of certain practices of classification and enumeration instituted in the context of colonial administration that gave a dominant place to Brahmanical texts as representatives of Indian society. An important intervention made by McKim Marriott (1990) needs mention here. Marriott provided a significant alternative to Dumont's formulation, arguing that different transactional strategies defined the position of different castes – it was not a simple case of hierarchy versus equality but rather of a universe governed by a complex set of rules and strategies regarding matching, mixing, and marking through which different regional and local configurations of castes were generated. What was at stake for both Dumont and Marriott, despite their differences, was the representation of India as the 'other' of the modern West. They were much less interested in either the concrete historical processes through which institutions were formed or the contemporary changes in the caste system. It is instructive to compare this with the way that caste was rendered in the work of the Indian anthropologist, M.N. Srinivas. Srinivas's stake in the local and his deep concern with the way caste was shaping Indian democratic politics distinguish him from these authors.

The Stake in the Local

The decade of the 1950s saw the emergence of 'village studies' as an important genre of anthropological writing in India. For Srinivas, the village was an indispensable site for fieldwork because of the importance he attached to what he called the 'field view' as distinct from the overly textual view of the caste system. The two important concepts that Srinivas formulated with far-reaching consequences for the study of caste were 'sanskritization' and 'dominant caste.'

Srinivas contended that a preoccupation with textual sources had led many to assume that the caste system was a rigid hierarchical system. Attention to historical and ethnographic processes on the ground, on the other hand, showed that while individual mobility was severely restricted in the caste system, group mobility had always been possible for castes in the middle rungs through the process of sanskritization. This process referred to the ability of a caste group, which had achieved economic or political mobility, to stake a claim to a higher status by recasting its customs and rituals to correspond more closely to Brahmanical rituals and practices. The process of change in ritual practices and social customs was not open to everyone. However, when a caste was successful in acquiring a measure of economic or political power through physical mobility, opening up of markets, or changed political alignments, it could translate this into claims to a higher caste status. With the decline in traditional kingship brought on by the colonial rule, such functions were shifted to colonial authorities. It is one of the exquisite ironies of the colonial rule that when caste began to be recorded systematically in the census, it became a major source for claiming of higher status by various caste groups who adduced their sanskritic practices or their myths of origin as evidence of their higher status.

Unlike the concept of *sanskritization*, which assumed an interaction between local and regional levels, the concept of

the dominant caste emerged out of an understanding of local and especially agricultural society. Srinivas argued that the ritual hierarchy of caste notwithstanding, the dominant role in village life was played by landowning peasant-proprietor castes who were rarely Brahmins. The relation between these rich peasant castes and the other castes in the village was characterized as a form of patron–client relations. Thus, Srinivas argued that the horizontal solidarity of caste expressed by endogamy and commensality was counterbalanced by the vertical solidarity observable at the village level through patron–client relations. Many institutions such as fictive kinship within the village, ritual processes for creation of boundaries, and the division of labor and economic exchange, created the village as an economic, political, and ritual unit that established solidarities cutting across caste. As the general understanding of locality in the field of anthropological theory deepened, interest shifted to the mapping of specific histories through which localities were created. The search for overarching structural principles seemed less fruitful than understanding how the momentous changes that were taking place in Indian society impacted upon caste, at the local, regional, and national levels.

Colonial Constructions

Once the search for enduring structural principles gave way to historically grounded work, the colonial archive became an important source for understanding the nature of colonial rule and how it transformed the institution of caste. The processes of enumeration and classification played a particularly important role in this process. Although the predecessor states of the British in India did have apparatuses for counting, classifying, and controlling populations, these were tied to specific needs of the state such as revenue collection, or rising of temporary armies. The British colonial state instituted a new way of collecting information in the form of maps, settlement reports, revenue records, statistical information, censuses, folklore, and narratives, to name a few.

This new form of governance, or 'rule-by-records and rule-by-reports' in the felicitous phrasing of Richard S. Smith had a decisive influence on the shaping of caste identities in the twentieth century. In the processes of classifying and enumerating the population, the British did not start with caste as if it were a natural category found on the ground. In the early phases of colonial rule, the emphasis was on cadastral control. Statistics on land ownership, tenancy, crop production, and instruments of agricultural production were geared toward standardizing methods of revenue collection and it was by no means obvious that caste rather than village would be the obvious unit for the organizing of data. According to Smith, it was only around 1850 that the census in the case of Punjab was transformed from an instrument of tax to an instrument of knowledge. Earlier census reports were more pragmatic and local in orientation. There was considerable tension between the concerns of centrist census officials collating data in an encyclopedic manner and the local officials who were concerned with recording the nature of social groups and categories for more practical purposes such as collection for revenue or settlement of disputes (see Appadurai, 1996). In order to understand the concerns of the centrist census officials who recorded information on caste for which there could have been no practical use, it is necessary to turn to the notions of race in the scientific discourses of this period.

In shifting to castes as the most natural groups around which information was to be organized on Indian society, British officials relied on their notions of race and physical types. Herbert Risley (1969[1908]) was the most vocal proponent of using anthropometrical measures in conducting the ethnographic survey of India because, according to him, anthropometry yielded particularly good results in India by reason of the caste system, which allowed marriage only within a limited circle. Relying on such symbolism as that of dark versus light skin color and shape of nose and jaw, the category of caste was thus collapsed with that of race. Ghurye (1932) was the first Indian sociologist to criticize this view of caste and to challenge its political implications.

It is not anyone's case that the process of recording caste created this institution *ex nihilo*. What it did was to freeze the ongoing processes by which caste came to be solidified in the official imagination, and to generate the conception of community as enumerative, which had a strong influence on processes of political representation (Cohn, 1984). It is important to underscore the fact that the census, gazetteers, reports, and other such forms of knowledge came to represent the power of official discourse to name and fix the status of caste groups in local imaginaries. Many caste groups began to see the census as the source for claiming higher status. Thus census commissioners were besieged with petitions challenging a particular status ascribed to a caste.

It is also interesting to see that the theories of the racial origin of castes had a serious impact on social and political mobilization, as in the anti-Brahmin movements in the South of India and in the mobilization of the untouchable castes under the leadership of Ambedkar in Western India – both of which used the idea of original settlers versus Aryan invaders. The discursive formations around caste quotas in educational institutions, government jobs, and reserved constituencies, as well as the politics of mobilization around these issues, show the interaction and circulation of categories between popular imagination and official discourse (Dirks, 1992).

The Contemporary Context

An important paradox about caste in public life in India is that while the Constitution of India recognizes only individuals as bearers of rights and duties, and bans any discrimination based on caste or religion, the processes of democratic politics with the imperatives of grass root mobilization have created new arenas for the evolution of caste-based politics (Bèteille, 1996; Kothari, 1970). Interestingly, the legal prohibitions on caste and the political mobilization around caste reflect the contrary pulls of formal legal justice system and the imperatives of representational politics in contemporary India. This can be illustrated with the example of 'untouchability' and its contradictory careers in law, politics, and everyday life (Galanter, 1972). It is not that a similar exercise cannot be done on other castes, but the example of untouchability has a particular resonance because of its unique association with the caste system.

While it could conceivably be argued that some form of caste-based discrimination is to be found in all the legal sanskritic texts, recent examination of the genealogy of the terms through which untouchability makes an appearance in discourse shows the importance of political and social processes in the negotiation of group identities in democratic societies (Charsley, 1996). The term 'untouchability' is ascribed to Sir Herbert Risley (1969[1908]) and was part of his effort to classify and rank castes in the subcontinent as a whole. While the category *shudra* occurs in the Sanskrit texts and is sometimes taken to be equivalent to 'untouchables,' its referents are varied – ranging from kings, powerful land-owning castes, to castes with extreme disabilities. Prior to Risley, compilers of district gazetteers and state census reports had experimented with other terms, such as depressed classes, depressed castes, *panchamas*, *pariahs*, etc.

The use of the term 'untouchable,' in public life, owed much to the reformist politics of early twentieth century, especially to Gandhi's politics of reform and the agenda for the abolition of untouchability in the nationalist movement (Gandhi, 1954). In 1931, Gandhi adopted the term *Harijan* (people of god) and increasingly substituted it for other terms in his writings. While the prototypical Harijan for Gandhi was a member of the *bhangi* caste who cleaned lavatories and was thus rendered 'unclean,' his major political opponent, Ambedkar, who himself came from the Mahar caste of Bombay Presidency, was much more interested in forging political alliances between the major agricultural-dependent castes, whose low status came from their dependency rather than their polluting occupations. Yet he preferred to retain the label 'untouchable' in his politics (Charsley, 1996). In the embroilment of nationalist politics with caste mobilization, Gandhi's strategy was to retain untouchables within the fold of Hinduism while Ambedkar's attempt was to forge a new identity for them, but within the Indian civilizational context – hence the choice of neo-Buddhism as the new religion for the erstwhile untouchables (Ambedkar, 1946). The term 'untouchable,' like other such generic terms, masks considerable local heterogeneity. Its importance lay in the binary division between untouchable and nonuntouchable castes created through the bureaucratic imperative of creating a single category for purposes of reservations. Under the Government of India Act of 1935, the term 'scheduled castes' replaced the earlier category of depressed classes. Although untouchability was to be the criterion for inclusion of castes into the list of scheduled castes, the names of the castes that were finally included in the state lists formed a kind of unity only through a "common relationship their members have with government" (Dushkin, 1972: p. 166). The fact that the category of untouchability was basically a twentieth-century creation does not detract from either the experiences of oppression of castes grouped under this category, or the importance of the grounding of struggles for greater equality under identity politics. In fact, the creativity of the new social movements can be seen in the emergence of the term Dalit (literally 'downtrodden') among the neo-Buddhists and scheduled castes in Maharashtra, which has become now the most commonly accepted term of self-reference by such groups. The most interesting feature of this phase of the movement of Dalits is the emphasis not only on political action but also on representation of the experiences of untouchable castes through literature, life histories, and collection of oral literature as a critique of caste society (Murugkar, 1991; Omvedt, 1995).

An interesting question arises as to whether politics is the only domain within which the legacy of oppression and humiliation is articulated in contemporary India. How are caste identities performed in everyday life? Khare (1984) had suggested that instead of playing the impure foil to the Brahmin, the untouchables conduct themselves even at the community level as civilizational critics, showing a complex relationship with caste ideology. Other important ethnographies of caste show how caste identity is performed in relation to everyday activities of work and worship, how elaborate strategies for management of caste identities are evolved, and how these performances come to be experienced as forms of embodiment. Debates on caste have shown the intricate relations between forms of aesthetic, political, and social representations of caste. Simultaneously, much of the scholarly agenda of research in India in recent years has been influenced by the public controversies on such issues as caste-based reservations or reintroduction of caste-based enumeration for the next decennial census. New patterns of sociality are evident in ways in which caste identity is performed in the context of family, community, economy, and polity, which reconceptualize caste not as a sign of the *exotic* but of the *contemporary* repositioning of the subjects and objects of anthropology in new ways.

Dalits, History, and Modernity

New directions in the understanding of the Dalits and caste oppression, as well as an independent Dalit perspective on modernity emerged as Dalit intellectuals have succeeded in reorienting the scholarship on caste. Simultaneously, there are important changes in the political landscape since the 1990s, signaled by the growing importance of Bahujan Samaj Party and its iconic Dalit leader, Mayawati, which have created the conditions under which new and controversial questions about Dalit identity can be raised, including by Dalit intellectuals and literary figures themselves.

There seems to be complete agreement among scholars that the prominence of Dalit literature has been crucial for bringing the experience of everyday humiliation as well as the brutal violence against Dalits into the public sphere by the literary device of testimonios (Ganguly, 2009; Rege, 2006; Bhagwan and Feldhaus, 2008a,b). Careful historical scholarship has been brought to bear on the manner in which classification and representation managed to eclipse the role of particular untouchable castes in historical struggles. Thus, Rawat (2011) shows the historical processes through which the Chamars, who worked as agricultural labor, were assimilated into the category of leather workers in the colonial classifications of caste and viewed as a criminal caste. In nationalist discourses too, their contributions to peasant movements were not recognized because they were not seen as a peasant caste. Rawat shows how some contemporary scholars have been quick to assume a stable composite caste identity of lower castes (Dalit-Bahujan) that is projected back to immemorial times. Such formulation obscure the intensification of

conflicts between members of previously untouchable castes and the middle-level agrarian castes that are now subsumed under the category of other backward castes. Narayan (2011) too makes the point that Dalit identity is not necessarily a stable identity – which is not to say that identities carved through experiences of making collective political subjectivities are inauthentic, but to signal the future openness of these constructions. Rao's (2009) careful historical reconstruction of the way that Dalit political subjectivity emerged through the nineteenth- and twentieth-century struggles shows how suffering might be transformed from a politics of resentment to a politics that claims agency through contestation.

The second important set of questions relates to the impact of various legislative and administrative measures to prevent caste atrocities on intercaste relations. Here, the folding of gender into caste is significant. Rao (2011) analyzes the cases of atrocity including infamous cases of rape and murder and concludes that scheduled caste women were seen as the property of upper caste men and that women were specially targeted for spectacular and public punishment for defying upper caste men and their sexual control over their bodies. In a later work, Rao (2009) adds more nuance to this argument as she argues that despite the good intentions behind laws to prevent upper caste violence against lower castes, especially Dalits, they can have the effect of revitalizing archaic practices. As laws that single out violence against scheduled castes become broader in scope, they constitute the Dalits as vulnerable subjects already subject to injury and thus might perpetuate caste stigmatization.

While on the one hand, it is clear that caste violence has become more intensified in areas in which the socioeconomic difference between upper and lower castes has narrowed (Sharma, 2012), it is also the case that studies of everyday life in areas reveal interesting contradictory trends. One survey designed by Dalit intellectuals and implemented by Dalit surveyors in two blocks in Uttar Pradesh found that Dalit households expressed greater satisfaction with their lives as compared to that of their parents. This was attributed in large part to greater accessibility of consumer goods and participation in markets (Kapur et al., 2010). In another case in a predominantly scheduled caste neighborhood in Delhi, Das (2011) found that connivance between local big men belonging to one's own caste and appointed officials surfaced in accusations of corruption and manipulation of government schemes to benefit residents so that the residents saw their own leaders as engaged in massive deceptions and exploitation. The Dalit perspective on modernity, it is argued, is not informed by valorization of tradition (Guru, 2000) as is evident in the desire for new kinds of goods or the desire for learning English (Dasgupta, 2000). Yet Dalit intellectuals as well as other scholars might have been too quick in dismissing what it is to be attached to tradition because of a rather simple view of tradition.

A more complex view of everyday life that incorporates heterogeneous elements from tradition is evident in the work of anthropologists and literary scholars who have been more attentive to the multiplicity of subject formations. Consider the work of Singh (2011) who found that the relation between Sahariyas in Rajasthan (classified as a scheduled tribe and some regions and scheduled caste in others) and the local landowning castes over the bonded labor issues might be best interpreted in terms of agonistic intimacy, in that same people who were involved in intense conflicts in the arena of politics were drawn to each other in ritual and worship through the mobility of their gods. In a bold move, Ganguly (2005) argued that the normative modernity that informs the conceptual legislation of the social sciences does not allow other conceptual positions through which attachment to caste might be viewed as a mode of dwelling and belonging. She proposes a shift from the ideological (caste as oppressive) to the phenomenological that can account for both pain and attachment to one's mode of being (however defined) within the everyday. Such a view would neither obscure the injustices and oppression to which members of lower castes are subject, nor assume that the practices of one's caste are all treated as stigmatized. Betlem (unpublished) offers a very interesting and thoughtful example from her study of the custom of dedicating young girls to the goddess among the Madigas (a Dalit caste) in Andhra Pradesh – a custom that is considered to be 'repugnant' by the reformist state because of the fact that the girls then become sexually available to higher caste patrons. Betlem shows that members of the Madiga caste display a complex subjectivity in which they simultaneously participate in the reform projects of the State and in the ritual performances through which the goddess is placated, negotiating multiple transactions within the self. Finally, we should note that such complex constructions of the self are found not only in the relation that Dalit castes have to Hinduism but also to Christianity. The fine study on caste and Christianity by Mosse (2012) demonstrates how Dalit Christians contributed to a distinctive culture of protest in the Tamil region drawing the Church into caste politics of the region. Simultaneously, however, Dalit festivals have been incorporated in the ritual calendar of many local churches and the appeal by Dalit priests to incorporate an Indo Dalit Christian rite within the Roman Catholic Church distinct from the Latin rite points to complex forms of attachment that put the entire question of tradition and modernity in a different light than a notion of modernity embedded exclusively within consumption would suggest.

Abstract

Manuel Castells Oliván is a highly cited sociologist born in 1942 in Hellín (Albacete), Spain. He began his academic training in Spain, but left for political reasons in the 1960s and continued his very active life and higher education in Paris. In 1979 he began to develop his academic career in the United States at Berkeley and other universities. His scholarly contributions are in the field of urban sociology and, from the beginning of the 1990s, in globalization and information and communication technologies. His work can be characterized as situated within the context of praxis, downplaying disciplinary scholarly development and focusing more on the identification of social and cultural inequities, and solutions to those inequities.

An Active Lifestyle

Manuel Castells Oliván was born in Hellin, Albacete Province of Spain on 2 February 1942. His mother, Josefina Oliván Escartín, was Aragonese from Biescas (Huesca), and his father, Fernando de Castells Adriaenses, was from Valencia. In a sense, it was a coincidence that he was born in the La Mancha region of southern Spain, where his father had been stationed. Later, Manuel Castells lived in several other places as the family moved because of his father's job. In his adolescence and youth he moved between the provinces of Valencia and Barcelona This article has been drawn from three types of sources. The first source is the two 'official' Web sites of Professor Castells, his professional web at the University of Southern California, Annenberg School for Communication and Journalism, http://annenberg.usc.edu/Faculty/Communication%20and%20Journalism/CastellsM.aspx and his 'scientific web,' a project financed by the University of Catalonia and the Fundación Telefónica, available at http://www.manuelcastells.info/es/index.htm. In the latter, Castells has updated and detailed the whole of his academic and professional activity. The second source of information consists of Castells' own texts as well as articles, monographs, anthologies, and published popular works from various stages of his life. Finally, the third source is a set of research materials available on various Web sites such as videos, interviews, conferences, etc., along with this author's own observations and interactions with Professor Castells on two occasions, first his appointment as an honorary member of the Spanish Federation of Sociology in Madrid in 2010 and second, the World Congress of Sociology, 2010 in Gothenburg.

Although Manuel Castells does not usually talk about his family or childhood, on several occasions he has said that he came from a very conservative and Francoist (supporters of the Spanish dictator Francisco Franco) family, which was common in Spain at that time. This background, undoubtedly, conditioned his subsequent development, his selection of topics for analysis, and his construction of theories about the world and society. It is possible that he inherited a strong sense of realism, with both feet firmly on the ground, and the critical spirit that characterizes him, from his 'Altoaragonese' mother (Altoaragonese are people from the North of Aragon. This includes the different valleys of the Pyrenees). His concern about power and the search for freedom probably have much to do with his sanguine, active, and sensual temperament and enjoyment of life, which put him up against the authoritarian ways of Francoist society of that time. He himself has said in interviews that he was an active, dynamic, and lively student, who found himself constrained by an authoritarian society and political regime. This made him leave Spain and look outside for what he could not find in Spanish society in the 1960.

At the age of 16 he began his university studies in Barcelona, in the field of social sciences and law. However, he could not study Sociology because it was not institutionalized until the 1970s, although several Sociology Chairs had existed in Spain from 1898. (In 1898, Prof. Manuel Sales y Ferré (1843–1910) was awarded the first chair of Professor of Sociology at the Spanish University Complutense of Madrid.) His initial training focused on law and economics from 1958 to 1962. At the age of 20, without concluding his studies, he was exiled to Paris. He resumed his studies in 1964 obtaining a License (Masters) in Public Law and Political Economy at the University of Paris.

He continued his education and in 1965 received a Diploma in Sociology of Work from the Institute of Social Sciences of Work at the University of Paris. In 1966, he obtained the Diplome d'Etudes Approfondies (Masters) in Sociology, Ecole Pratique des Hautes Etudes, University of Paris. This was followed by a Doctorat 3eme Cycle (PhD) in Sociology from the University of Paris in 1967, a Doctorate (PhD) in Sociology from the Universidad Complutense of Madrid, and a Doctorat d' Etat in Sciences Humaines from the Universite de Paris-V, 'Rene Descartes – Sorbonne.'

His capacity for work and sound training achieved in the field of sociology, under the tutelage of his teacher Alain Touraine, enabled him to be a researcher and assistant lecturer in France, firstly from 1965 to 1967 as Researcher at the Laboratory of Industrial Sociology at the Ecole Pratique des Hautes Etudes in Paris, then from 1967 to 1969 as Assistant Lecturer in Sociology at the University of Paris (Nanterre Campus). It is said that his classes were a key place for the French students who mobilized in May 1968. This, however, meant that he had to leave France for a while from 1969 to 1970, taking up the post of Assistant Lecturer in Sociology at the University of Montreal (Canada). He returned once again

to the French university as Associated Professor in Sociology (with tenure), and director of the Seminar for Urban Sociology, *Ecole des Hautes Etudes en Sciences Sociales* in Paris, from 1970 to 1979.

He was Professor of City and Regional Planning and Professor of Sociology at the University of California at Berkeley from 1979 to 2003, engaging in various tasks such as teaching, research, and management, which led him to affiliation with a wide range of centers and institutes at Berkeley that focused on Western European Studies, Slavic and Eastern European Studies, Environmental Design, and Southeast Asian Studies. In addition, he combined these duties at Berkeley with posts of Professor of Sociology and Director of the Institute of Sociology of New Technologies at the Universidad Autónoma of Madrid (1988–93) and with his position of Research Professor, Consejo Superior de Investigaciones Cientificas, Barcelona (1997).

As of 2013, he held positions as Director of Research, Professor and Professor Emeritus in four different institutions: Cambridge, University of Southern California, Open University of Catalonia, and University of California at Berkeley.

Social Scientist

Castells has said, "I am against disciplines including sociology, economics, anthropology, I believe that the world is complex and can only be understood from an interdisciplinary approach (…). I don't believe in disciplines." (Taken from the Radio Televisión Española (RTVE; Spanish State Radio Television) documentary 2013, http://www.rtve.es/television/20130612/sociologo-manuel-castells/686369.shtml.) His words, while they contain a contradiction because to speak of interdisciplinarity, the distinctions that apply to each discipline are necessary, allow us to understand, to some extent, the changes and the evolution of his career as a researcher and teacher in the field of social science. His initial training, as shown in the previous section, started in the field of economics and law, and then passed through sociology, political science, and humanities, and is currently in the field of communication. Manuel Castells himself has pointed out, "When something matters to me and I don't understand it, I become a professor of this in order to learn." Perhaps this is the key that has resulted in him becoming one of the most cited academics of the early twenty-first century.

Internationally, despite his statements of interdisciplinarity, Castells is recognized first, as an urban sociologist, second, from the late 1990s, as a referent in the sociology of globalization and information and communication technologies (ICTs). In fact, the field of sociology, it could be said is his primary field, however his success has been to go beyond the limits of the discipline(s) to address social reality itself as an object that requires customized empirical attention and comprehensive effort in its completeness.

For Castells, his approach is not to 'jibarize' (minimize) the object of study and to compress it into preconceived models, but to study the concrete by going beyond abstract models: from empirical to theory, and not the reverse. His methodological position is that any explanation and analysis, if it wishes to be scientific, must be based on data and observation of phenomena to explain and analyze, but not just models. It is a task, a work of intellectual construction that starts from observation, collects data empirically, submits data to an analysis methodology, and then proceeds to an intellectual reconstruction preparing a statement that makes sense and is not just a statement, but gives sense to an observed reality.

Castells advocates the empiricism of praxis in touch with the world, in the face of the sophist temptation of empty words grounded in previously established abstractions. As he has explained publicly, his doctoral thesis at the University of Paris dealt with 'the determinants of the location of industrial enterprises in the metropolitan area of Paris, a statistical model of analysis of 1500 companies' and he points out "there is nothing more concrete and statistical" (RTVE documentary). Castells says he has always been empirical.

Manuel Castells, therefore, emphasizes the need for empirical observation that focuses analysis and makes rigor possible, because you cannot say anything, "what you say has to relate to what you observe" (RTVE documentary). He goes a step further in his approach than mere empirical verification to opt for an 'intellectual framework' because it has a criterion of coherence and relevance in the process of explaining phenomena.

Urban Sociologist

Castells' current rejection of preconceived models that simplify social reality is an evolution from his early works. In his youth he shared a Marxist approach where the solution is already known due to observation being limited by the Marxist-defined coordinates that see conflict and class struggles such as the role of social movements in urban transformation (Castells, 1976). His contributions to urban sociology brought him significant international importance. He is credited with introducing the concept of 'collective consumption' (Castells, 1974a; Castells 1975, 1976), as a way to study changes in the management of social struggles, moving from the realm of the economic to the political because of state intervention. This focus on the political was another way of studying the faces of power; something that continues to occupy him and which he regards as central in his academic and research career.

Castells considers himself as an advocate and member of the 1970s 'new urban sociology' (Castells, 2012, Holberg Prize Ceremony) (Elliot, 1980), where power – conflicts, politics – and not just spatial forms were the central issues. Included in this group were Lefevre, Harvey, and a few others, who left behind the Chicago School's concern for 'urban integration.' In this early stage as an urban sociologist he produced an important list of books and articles. One of the most provocative 'Y a-t- il une sociologie urbaine?' was translated into English in 1976 although published in French in 1968 in the newly created magazine *Sociologie du Travail*. Other works that stand out include *Problemas de investigación en sociología urbana* (1971), *La Question Urbaine* (1972), the collection of essays City, Class, and Power (1978), *Urban Crisis and Social Change* (1981), and *The City and the Grassroots: A Cross- Cultural Theory of Urban Social Movements* (1983).

His research on the subjects of urbanism, urban planning, structure of cities, industrial areas, organizations, and issues

that revolve around the city, social movements, and power structures also led him to be concerned about social and economic development in Latin America and Asia. From this it is also possible to trace his gradual transition to studies on globalization and its attempt to respond to the new challenges that have emerged, in that the city and society have been transformed at the hand of the so-called ICTs.

Thus, in 1989, he published *The Informational City. Information Technology, Economic Restructuring and the Urban – Regional Process* and an article entitled *Social Movements and the Informational City* that can be considered to be key references in the evolution of his work. Castells puts forward the concept of *space of flows*, which is described as "the material organization of time-sharing social practices that work through flows" (Castells, 1989a, p. 147). From this conceptualization, an almost natural transition is articulated from his studies in the field of urban sociology to the new dimension of a globalized world where ICTs become the backbone of its new research and publications.

Informational Society

For Castells, in the 'information age' it is not intellectually correct to speak of the information and knowledge society. All human societies are based on both pillars, processing them in particular ways according to the time and circumstances. He prefers to say 'informational,' that is, "the use of a new technological system based on ICTs with microelectronic support and of communication through digital networks" (RTVE documentary, 2013).

From his viewpoint, this technological framework changes the mental and communication processes of human beings. ICTs cause a material change in relation to how we process information and communicate. Castells is among those, including Niklas Luhmann and Gordon Pask, who emphasize that communication is the essential element of human interaction and that meaningful communication is the key to our social relations. Castells, however, appears to discover a novel way that had not been explored that focuses on that we are in an era where microelectronics have changed the forms, rhythms, and communication mechanisms so that the human mind has become radically transformed. This means that we are faced with a new scenario: a great transformation that generates a new digital culture, where the convergence of cultural change and technological change revolutionizes society.

Castells posits that his arrival in Berkeley allowed him to see firsthand the consolidation of the digital information industry in the Silicon Valley, and witness the emergence of this process of transformation that is now on another level. In a sense, he was in the right place at the right time. He was present at the electronics and information explosion, seeing emerge what now seems obvious: a new technological system affecting all and producing the electronic revolution.

Manuel Castells argues that these structural phenomena such as technological change, digital culture, and globalization require various viewpoints. Different approaches from different cultural positions are needed to see their interdependence. It can only be explained in this way, knowing that there has been a radical change that transforms the present and the future of humanity. Castells argues that 97% of information is digitalized, therefore accessible by electronic means and the network. This leads him to pass from the diagnostic and the empirical description of the world around us to the proposal and the prescription of what one should do. It could be said that he moves from science to consciousness and then to political praxis, in the best sense of the word. He considers that, faced with this overwhelming circumstance produced by the excess of available information, where a person can become paralyzed without knowing what to do, one has to pass from passive consumption in the network ocean, to navigation, with direction and orientation. He proposes that everyone becomes active creators of information and communication.

Castells finds an example for this issue in the social (wiki) movements of occupation and rebellion produced in different places and countries. Here he observes how the use of available ICTs has made other forms of organization possible. The people involved in these social movements deploy deliberate and nonhierarchical forms precisely because technology allows these forms of communication. This is the underlying current in his work, *Networks of Outrage and Hope: Social Movements in the Internet Age* (2012).

For him, the Internet arose as a social media, with the intention of connecting with others. Castells argues that the Internet is not an information system, it is a communication system (RTVE documentary, 2013). He attributes elements of passion, innovation, and altruism to the network and downplays its military and power control origins. However, apart from this detail, he has also called his 'informational society' a 'network society.' The essential work for understanding his position is the trilogy *The Information Age: Economy, Society and Culture*, consisting of the volumes *The Rise of the Network Society*, *The Power of Identity*, *End of Millennium*. The first edition was published between 1996 and 1998 and the second edition, extensively modified, between 2000 and 2004, this work is considered by many to be one of the key references in global sociology and has placed him among the most important authors. It is, in fact, one of his most cited works. However, his critics say it is only a more or less successful compilation of other authors, where the only novelty is the actual summary made. Castells has continued his research and publications in this field and of his works written in 2006 the following are of note, *The Network Society: From Knowledge to Policy* and *Mobile Communication and Society: A Global Perspective*.

Power and Change

Manuel Castells describes his work as coming from the same vertebral axis, the same line of argument, namely, the question of power. For him, it has been a central theme in his personal development and career. As he stated in an interview in 2012: "My analysis of power. This has been the overarching theme I have studied in my works, in many contexts and in different domains of society. Power in the city. Power in and by information technology. Power in globalization. Communication power, that is the power and counterpower built in the media and in the Internet networks. In terms of specific themes I think that what will remain from my work is to have been able to map out economies, societies and culture at the dawn of the information age, coining the concept of the network society as

a key thread to understand the transformations brought about by the digital revolution in interaction with the culture of autonomy, and the globalization of the economy" (from the Holberg Prize interview with Manuel Castells, http://www.holbergprisen.no/en/manuel-castells/interview.html).

His analysis of the phenomenon of power is posed as an empirical question on which he elaborates theory, but from an instrumental view of theory. For him, "theory is useful to produce knowledge through research, different kinds of research. But it is not a goal in itself" (Lecture by Manuel Castells at USC Annenberg about Network Theories of Power). This is key to his overall research strategy and, in particular, in the study of power. Castells says "that power is based on the control of communication and information, be it the macro-power of the state and media corporations or the micro-power of organizations of all sorts" (2009: p. 4).

He is interested in the question of power because those who have power model and control society. He states that power is the matrix of rules that constitute society. He defines power as "the relational capacity that enables a social actor to influence asymmetrically the decisions of other social actor(s) in ways that favour the empowered actor's will, interest and values" (2009: p. 10). Additionally, Castells argues that resistance as a counterpower always appears where there is power and domination. An important component in his study of power is his extension of existing theories of power to four forms of power in networks: (it is possible to listen (directly) to Manuel Castells explaining this at http://www.youtube.com/watch?v=skcUYhRaEas) (1) networking power, (2) network power, (3) networked power, and (4) network-making power.

In his research on the question of power there is an implicit proposal of utopia. On its particular horizon is freedom as a supreme value. It is what allows everything else. Equality yes, but without freedom one cannot fight for equity. He calls for real democracy, now, which overcomes inertia and uses current tools provided by ICTs. For instance, ICTs can help achieve new forms of democratic representation through increased communicative autonomy; the social sciences contribute to this new form of social change.

For Castells, power has no abstract or theoretical nature; it is in the specific hands of individuals, organizations, and networks. He asserts that you cannot make general theories, only specific analysis of particular cases. For him, the most important issue is the creation of meaning; those in power have the ability to program the socially available meanings. Therein lies the true power. This reveals the road of change, and as a result of this he takes the position that because everyone develops their critical spirit, and from here seeks cooperation and the network to be together, get value, lose fear, and take the step to being able to act and change, with the fundamental principle of nonviolence. It could be said that he has discovered the French saying: *Tout se passe dans la tête*. What Castells seeks is a utopian freedom from below and from the Internet that changes the world as we know it for the better.

Conclusion

Manuel Castells has received over 40 awards and honors ranging from his first award, the John H. Simon Guggenheim Fellowship in 1982–83, to his most outstanding and most recent, the Holberg International Memorial Prize from the Parliament of Norway, in 2012, and the 2013 Balzan Prize for Sociology. His contributions, first, in the area of urban sociology and, second, in the field of ICTs have positioned him throughout the world as an author of reference. His work has been innovative and visionary in many ways. He could be considered thus a key figure in the construction of international sociology, and continues to be active in producing and generating significant contributions for a better understanding of the current world. He has generated a substantial theoretical corpus with his publications.

His work does not stop with publications, Castells has sought to take up a position and excel in all processes of 'revolution' and change that have taken place close by. These have included the demonstrations and sit-ins arising from 15-M in Spain. (Watch him and listen to his own words at http://www.youtube.com/watch?v=iUsNhz9Vxkk.) His activities emphasize his multilocal character; "after being expelled from several countries, whenever there was a dictatorship I was going to fight it and they end up expelling me" (RTVE documentary, 2013). This inclination to fight against power and the powerful is admirable, though it also provides a ready lead into questions that arise regarding his contributions to a solid and cohesive body of scholarly knowledge about power and organizational processes.

While many followers of Castells see in his work and person a figure equivalent in contribution to the social sciences as Karl Marx, Max Weber, or (more recently), Bourdieu, Luhmann, Habermas; others raise concerns about the impact on knowledge creation of Castells' prioritization of empiricism and flexibility over discipline-based theory. (It is possible to listen to him on http://www.rtve.es/television/20130612/sociologo-manuel-castells/686369.shtml. Some examples of a type of 'adoration' and idolization can be found at 7′57″, 15′, and 17′ 31″. In the last example Imma Tobella said [*sic*]: "Castells demonstrated that he is the Max Weber of XXI century.")

Regarding empiricism and flexibility, one could say that Castells advocates the empiricism of praxis in touch with the world and implicitly characterizes a focus on discipline-based theory as using empty words grounded in previously established abstractions. As he has explained publicly, his doctoral thesis at the University of Paris dealt with "the determinants of the location of industrial enterprises in the metropolitan area of Paris, a statistical model of analysis of 1500 companies" and as he emphasizes "there is nothing more concrete and statistical."

However, it could be said that his epistemological and methodological perspective has remained in a first order observation, where there is not a review process and critical reflection on the way in which observer and observed produce the observing process. The world is given, you only have to look (outside). This approach, from a Sociocybernetical perspective (Marcuello, 2006) or from the Subject Oriented Approach of Arne Kjellman (2003), lacks sufficient epistemological sophistication. As described by Van Dijk (2010) Castells approach is fuzzy and unclear, where meanings and psychology appear in his particular repertoire of concepts without giving a coherent and solid theory. Castells analysis lacks a more comprehensive

review of other approaches that add more complexity to complicated and complex issues. This lack of complexity is critically important in his way of studying power, or rather, power relations, which continues to retain a dichotomous perspective where it is clear that there are some who command because they have power and others who obey and resist because they do not. Old patterns are repeated under an undeclared Marxist approach, but the elements of complexity that the modern social system produces are obviated.

It is true that the work of Manuel Castells is vast and significant. However, if his work is analyzed and compared with other great social scientists, questions arise as to whether he will be considered to be of the same standing as either classical or contemporary figures of sociology. Only the passage of time will tell if his work has enough density to establish itself in the History of Ideas and be a landmark reference.

Abstract

Catholicism, meaning universality, signifies the central form that Christianity has taken in history from the second century onward, a form shared by all the main early traditions – Greek, Latin, Syriac, Armenian – including hierarchy, sacraments, religious orders, the cult of saints. From about the eleventh century, however, the 'Catholicism' of the Western church became increasingly clearly 'Roman Catholicism,' dependent upon the exercise of papal authority and the extension of Roman Canon Law, an ordering of ecclesiastical life different to the 'orthodoxy' of the eastern churches. Challenged by the Reformation, the medieval form of this Catholicism was only strengthened by both the Counter-Reformation and the papal supremacy (Ultramontanism) of Vatican I in the nineteenth century. It was, however, profoundly altered by the reforms of Vatican II and is now in a state of contestation between those who appeal above all to the latter, reincorporating Protestant Reformation insights, and those who, on the contrary, believe that Vatican I still provides the decisive model.

Catholicism signifies the central form that Christianity has taken in history from, at latest, the second century, but it is a form that has continued steadily to evolve. In the second millennium Catholicism has come to designate most particularly the character Christianity has assumed within the Roman Communion under the authority of the papacy.

'Catholic' is not a term to be found in the New Testament but it is already being used to characterize and designate the church in its early postapostolic period. Its primary meaning is 'universal,' signifying both Christianity's claim to be a faith unbounded by language, ethnic, or class boundaries and the insistence that local church communities must be in communion with one another: the church in Corinth or Ephesus is 'Catholic' because part of an association of communities sharing the same faith and rituals present up and down the Roman Empire and, potentially, everywhere. As such the term quickly became the church's most regularly used name, incorporated into the creeds. All Christians using the creeds, whether Roman Catholic, Orthodox, or Protestant, claim to believe in, and belong to, the Catholic Church.

The character assumed by Christianity in the second century and generally termed 'Early Catholicism' is one in which each local church is ruled by a bishop, assisted by priests (presbyters) and deacons, claiming 'succession' from the apostles. Entry is via the sacrament of baptism while regular worship is centered upon the weekly celebration of the Eucharist, renewing Jesus's last supper with his disciples. The Hebrew scriptures were retained as inspired, generally in their Greek Septuagintal form, to which was added a collection of the earliest Christian writings, the New Testament, to which apostolic authority was attributed. The shape of Catholicism had, however, been established well before the full canon of the New Testament was agreed upon, certain books remaining for long in dispute. While there was at first no formal machinery for linking local churches together in the one church, local councils of bishops from neighboring towns soon began to be called, while the churches in major cities, particularly those claiming an apostolic foundation, assumed a leading position. Among these the Church of Rome, where both Peter and Paul were martyred, came to be accorded an unquestionable preeminence from an early date.

While all the books of the New Testament are centered unequivocally upon the figure of Jesus Christ, they already suggest, particularly in the account of the first Christian martyr, Stephen, but also in concentration upon certain of the apostles, the importance for early Christianity of the personal 'witness' to Christ (the strict meaning of martyr). A cult of the martyrs, focused upon their tombs, began early and developed into a wider cult of the saints that remained a permanent characteristic of Catholicism. Furthermore virginity/celibacy was stressed from early times as an alternative road to exceptional holiness, a way later institutionalized in monasticism.

This 'Early Catholicism,' constituted by hierarchical ministry, sacraments, the canon of scripture, and the cult of the saints, was common to east and west, the Greek and Latin churches, as also to Syrian, Coptic, and Armenian churches. Despite diversities of language, liturgy, and theological tradition, Catholic Christianity was held together by the fact and theology of 'communion,' a sacramental bond of fellowship from which individuals or whole churches could be excluded on account of heretical teaching or moral deviation.

After Christianity became a privileged religion with the conversion of the emperor Constantine in the early fourth century, it grew enormously in numbers. What had hitherto been a community of a voluntary sort whose members knew that they might well have to face persecution on account of their beliefs became instead quite quickly a church of the masses, many of whose members had received very limited Christian instruction. The myths and customs of the rural population were carried on, often covered over with a thin Christian veneer. Henceforth Catholicism would be characterized by the co-existence of a clerical and monastic religious upper class with a popular religion which it would preach to generation after generation but never fully convert.

Post-Constantinian Catholicism grew too in the development of an institutional framework designed to resolve conflicts and maintain unity, although the result was often to precipitate still worse division. The most striking development of this was what came to be recognized as the 'ecumenical council' beginning with that of Nicaea (325). At the same time the authority of

[†] Deceased

the major churches – Rome, Alexandria, Antioch, and then Constantinople and Jerusalem – was further accentuated. By the fifth century this had been stabilized in the theory of the 'Five Patriarchates' but, among them, Rome and Constantinople held a quite privileged position. That of Rome, with its unquestionable apostolic origins, had been there from the start, but was reinforced greatly from the late fourth century. Constantinople, the new imperial capital, claimed to be for that reason also the church's second see in dignity, though Rome denied that its own primacy was due to its civic, rather than its apostolic, status. In practice, the two co-existed for centuries, at times somewhat tensely, but also co-operatively. Rome enjoyed an increasingly effective primacy of jurisdiction throughout the Latin west but of little more than honor in the east. At the same time the advance of monasticism profoundly affected the ethos of Catholicism in both east and west.

It was only after the eleventh century that the 'Catholicism' of the western church could be distinguished clearly from the 'Orthodoxy' of the eastern. The Gregorian reform (named after Gregory VII, pope from 1073–85) profoundly affected the western church but through the accentuation of tendencies already present. Three are crucial: the first was a large extension in the claims but, still more, the effective jurisdictional power of the papacy. Its ability to impose a defined model of ecclesiastical life was turning 'Catholicism' into 'Roman Catholicism': a hitherto largely decentralized church was being made to conform ever more closely to rules laid down in Rome, rules which included insistence on higher moral and educational standards in the clergy and greater separation between clergy and laity. The second was a vast extension of canon law and its implementation through a hierarchy of church courts with appeal always possible to the highest courts in Rome. Canon law became the effective tool for implementing the new Gregorian ideals. The third was the law of celibacy for all the clergy. Hitherto most ordinary priests were, or had been, married, just as they had been and continued to be in the east. Henceforth in the west the married priest would be an offender, though in practice he would long continue to exist. The law of celibacy was a necessary tool for ensuring the segregation of clergy from laity, making it possible for the former to be controlled effectively by higher church authority. The 'church' became in practice more and more a clerical reality in which the laity were expected ideally to remain passive and obedient. The identification of church and clergy was accentuated further by language. The early church had allowed great linguistic flexibility but in the medieval west Latin came to have a wholly privileged position as the language of the church and its public services as well as of theology. As a range of vernaculars developed vigorously their own literatures, the ecclesiastical use of Latin became a further characteristic of Catholicism. It expressed a certain clerical universalism at odds with the national vernaculars used by the laity.

Two further developments, linked particularly with the thirteenth century, were also lastingly influential for the shaping of Catholicism and its differentiation from eastern Orthodoxy. One was the founding, beginning with the Franciscan and Dominican friars, of religious orders which were not purely monastic but, instead, active, mobile, and involved in the world around them, especially the urban world. Further societies of this sort, most notably the Jesuits in the sixteenth century, would multiply, providing a powerful, well-organized, and educated religious army at the service of the church, available not only internally but also for missionary service abroad, as the Franciscan mission to China in the fourteenth century already demonstrated. The second was scholasticism, formal systems of theology, heavily influenced by the rediscovery of Aristotle's works, which grew out of the teaching system of the new universities. Here formal logic was learned and applied in a systematization of theology very different from that of the patristic period or the continued traditions of the Greek east.

Thus, by the later Middle Ages the type of Christianity which we have come to call Catholicism was almost fully evolved – a mix of subapostolic, post-Constantinian, and medieval developments. The Reformation brought an attack on many of these developments, almost anything in fact which could not be defended with firm scriptural authority. Against this assault the papacy yielded almost nothing. It admitted moral and educational, but not doctrinal or institutional, failings. The Council of Trent (1545–63) formulated the lines of the Counter-Reformation position, emphatically reaffirming almost everything that Luther, Zwingli, and Calvin had impugned. The one major new element that it added to the character of Catholicism as a social reality was the seminary. Hitherto there had been no institutions formally established for the training of diocesan priests, who had learned what they needed to know either through the general education of a university or through a measure of apprenticeship, a son often enough learning the job from his father. The Tridentine seminary would improve greatly the effectiveness and education of the clergy but also further distance them socially from the laity, particularly on account of the 'minor seminary,' effectively a secondary school in which candidates for the priesthood would be segregated from their early teens. This could lead easily on to a further gap between the clergy and the university world, and therefore also between the clergy and modern ways of thought. While with time medieval scholasticism was ousted from the university, it would in a much degraded form continue to dominate the characteristic mindset of the clergy until the twentieth century.

Tridentine Catholicism was, nevertheless, far more creative than the term 'Counter-Reformation' might suggest. While classical Protestantism with its commitment to '*sola scriptura*' was averse to religious involvement in secular culture, the Catholicism of the sixteenth and seventeenth centuries produced its last great cultural era, the Baroque, as rich artistically as the earlier Catholic art cultures, the Romanesque and the Gothic. In art and music, as in theology and spirituality, Catholicism is by nature open to the secular and developmental, even luxuriantly. This was always true, though only in the nineteenth century did John Henry Newman justify the development of doctrine as a human and Catholic necessity, to be contrasted with Protestant insistence upon not going beyond the explicit content of scripture.

Sixteenth- and seventeenth-century Catholicism was also particularly fruitful in the literature of prayer, from the mystical writings of the Spanish Carmelites, Teresa of Avila and John of the Cross, to the Jesuit *Spiritual Exercises*, Francis de Sales' *Introduction to the Devout Life*, and countless other minor classics, many of them popular also among Protestants. Catholicism then has traditionally combined institutional rigidity with

spiritual and artistic creativity. In the nineteenth century with the triumph of Ultramontanism (a name used to describe a form of Catholicism in Europe north of the Alps anxious to enhance papal authority and uniformity with Rome in contrast with the more old-fashioned Gallicanism which accepted papal supremacy but limited to a minimum papal intervention in non-Italian ecclesiastical affairs) institutional rigidity grew while creativity declined. Faced with the often anticlerical, and even antireligious, ethos of the French Revolution and later liberal movements, the Catholic Church drew in on itself as a fortress against the modern world, defining the authority of the pope at the first Vatican Council of 1870 under Pius IX (1846–78) while a little later Pius X (1903–14) condemned every form of 'modernism.' In the first decades of the twentieth century Catholicism could then appear as a consistently reactionary force, intellectually, culturally and socially. Yet it was far from being a community in decline. Modern technology made Roman centralization work in a way never previously possible. The railway brought countless pilgrims to Rome and a cult of the reigning pope among ordinary Catholics quickly developed. Pius IX, antimodern as he was, became in consequence the first 'modern' pope, almost idolized by millions. At the same time a series of apparitions of the Blessed Virgin Mary mostly to children, of which the most famous were at Lourdes in 1858 and at Fatima in 1917, much reinforced a principal focus for Catholic popular devotion, both backed by and supporting papal definitions of Mary's Immaculate Conception (1854) and Assumption into Heaven (1950). The missionary orders, mostly nineteenth-century foundations, were extending Catholicism throughout the southern hemisphere; there was a move to encourage forms of lay apostolate across Europe and North America, while for the first time there had developed a vast army of nuns at work almost everywhere. This last may have been the most significant shift. In the Middle Ages nuns were few in comparison with monks and included no active orders. Only in the seventeenth century, led by heroic women like Mary Ward and Jane Frances de Chantal, did unenclosed orders of women, committed to apostolic work as well as prayer, begin to exist despite huge clerical opposition. By the close of the nineteenth century there were more nuns in the church than priests. Silent in many ways they were forced to remain, Roman Catholicism being traditionally an intensely male-dominated and clerical form of Christianity, but a changing balance between the sexes was evident even here.

Catholicism continued to present publicly an almost unchanged face until the end of Pius XII's pontificate in 1958; highly clerical, intellectually repressed, well organized, expansive, more tightly controlled from Rome than ever, insistent upon the use of Latin, retaining apparently untouched its medieval legacy, institutional, and liturgical. Yet processes of modernization had already gone far, intellectually especially in western Europe, institutionally elsewhere with the appointment of Asian and African bishops, and the creation of numerous cardinals to represent every continent. For the first time since the fourteenth century, the majority of cardinals were not Italian. It needed only the gentle touch of John XXIII and the calling of the Second Vatican Council (1962–65) for a truly revolutionary process to set in, only part of which was formally approved by the Council. The intellectual debate unleashed by 4 years of conciliar discussions set a movement in train which went well beyond the letter, though often not far beyond the spirit, of the Council's decrees. Within a few years Latin was replaced by the local vernacular in the liturgy and theological education; scholastic theology almost disappeared from the seminaries; hitherto frigid relationships with the Orthodox and Protestant churches gave way to a near-frenzied spate of official ecumenism.

In strictly theological terms the changes of Vatican II may seem less than revolutionary, but in the wider terms of the sociology of Catholicism, its sense of identity and shared ethos, they undoubtedly were. Symbolic ramparts, such as the denial of the cup in communion to the laity, which had been fiercely maintained against Protestantism for centuries, were dismantled quickly. It was not only that the barriers which made Catholics feel they were different – from Latin to Friday abstinence from meat – had almost disappeared, and with them the shared certainty that the pope was always right. It was also that Catholics now found themselves divided in a way that had never previously been the case in modern times. If, for Pope Paul VI (1963–78) and the official church, Vatican II had gone just far enough this was challenged from both right and left. For the former it had gone much too far, betraying authentic Catholic values in the pursuit of ecumenism, while for the latter it had failed through evading the most awkward issues, notably that of Roman centralization. The conflict hardened particularly over two matters that refused to go away: contraception and the law of celibacy for priests. Pope Paul had prevented the Council from discussing either. Contraception was passed to a papal commission that actually recommended a change in teaching. Paul rejected the recommendation and in 1968, in the encyclical *Humanae Vitae*, reaffirmed the use of contraception to be always wrong. He was quite unprepared for the degree of open opposition this aroused and for the consequent decline in confidence in papal teaching, particularly among the more thoughtful laity, who disregarded widely the papal ban. Again, despite numerous appeals, at least to allow married men to be ordained, both he and John Paul II (1978–) repeatedly renewed insistence on the law of celibacy in face of the near-catastrophic decline in the number of priests in the western world in the 30 years following the council, due both to the withdrawal of priests from the ministry, usually to marry, and a linked fall in recruitment. A further factor was that minor seminaries were now seen as obsolete and closed almost everywhere in Europe and North America in the early post-conciliar years. The credibility of the law had been internally undermined by several things: Vatican II's praise for the married clergy of Catholic Uniate churches in the east, its permission for married men to be ordained to the diaconate, and, finally, the acceptance of married priests, especially in Britain, if they were converts who had been ministers in another church previously.

Opposition to contraception set Vatican policy against almost all international attempts to curb the rapid rise in global population. This, together with papal rejection of the ordination of women and refusal to open the door to a married priesthood, did much to restore the nineteenth-century image of official Catholicism as incurably reactionary and anti-modern. At no time since the Middle Ages has the papacy appeared to matter so much within public policy as in the age

of John Paul II but its image has reverted to that of Pius XII. In papal history John XXIII could seem an aberration.

Shortage of priests resulted in the closing or merging into one of many parishes, especially in France, and the transfer of duties from priests to deacons or to the laity in general. Women, who in the past had never been allowed even to serve at mass, were now enrolled in thousands as 'eucharistic ministers.' Moreover, the religious orders, both male and female, whose numbers had grown enormously between 1850 and 1960, went into rapid decline in Europe and North America. In practice a rapid declericalization of the Church's ministry was taking place. While this could be seen as advantageous, its value was partially undermined by the haphazard way in which it happened, lack of a positive pastoral strategy and continued insistence by Rome that the traditional clerical pattern remained normative.

Behind the conflicts over practice and the loss of confidence in authority there were now huge differences in theological perception. If Vatican II seemed almost unbelievably radical to Catholics content with the church of Pius XII, the policies of John Paul II seemed almost unbearably reactionary to Catholics who had found the Council a harbinger of religious liberation. Many 'progressive' Catholics, while deeply loyal to the unity of a worldwide communion and to the idea of a central 'see of unity,' not only rejected much current papal teaching, particularly that of John Paul, whose personal theology often appeared fundamentally preconciliar, but had come to share so full a sense of fellowship with Christians of other churches that intercommunion had come to be seen as obviously right and was practiced frequently with the encouragement of many priests, despite condemnation by authority. 'Conservatives' accused 'progressives' of practicing an '*à la carte*' Catholicism. 'Progressives' charged 'Conservatives' with 'integralism,' confusing the substance of Catholicism with clericalism and Ultramontanism. While 'Progressives' tended to define Catholicism in terms inclusive of the principal insights of the Reformation as constituting a necessary critique of the one-sidedness of the late medieval church, 'Conservatives' continued to define it as inherently contradictory to Protestantism. Vatican II had, in fact, led to a profound questioning of the model of Catholicism as it developed across a 1000 years from the Gregorian reform through the Counter-Reformation to the decrees of Vatican I and Ultramontanism. How far that model will in consequence alter in the long run remains unclear.

It may well be claimed that the areas where this contestation is most in evidence are also areas of church decline. As against that decline, most obvious in western Europe, is to be set a huge growth of Catholicism in Africa, Latin America, and several parts of Asia. Brazil is now the country with by far the largest number of Catholics. Here too, however, there are great differences. Latin America has suffered an acute shortage of clergy for far longer than Europe and most of the issues dividing the church in Europe are evident here too, as also in the Philippines. The advance of Pentecostal Protestantism is also altering the hitherto almost exclusively Catholic character of Latin American Christianity. Elsewhere in Asia and in most of Africa the number of priests and religious has escalated. Religious orders whose recruitment plummeted after Vatican II in their traditional areas have grown remarkably in Africa, India, and Indonesia. For the Jesuits in particular India became the most flourishing of provinces, but the growth of houses of contemplative nuns in Latin America also is noteworthy. Nevertheless throughout the southern hemisphere there are profound tensions between Roman control and local processes of inculturation and political orientation. The future of Catholicism as the principal constituent within Christianity may depend upon how far a lasting *modus vivendi* is established between pope and Curia on the one hand and the young churches of the south on the other. John Paul's understandable preoccupation with Poland and eastern Europe is unlikely to be continued by his successors. Brazil, Argentina, India, the Philippines, Nigeria, and the Congo may matter more for the shaping of Catholicism in the twenty-first century than traditional pillars such as France, Spain, Ireland, and Poland, though the mediating position of the vast church of the United States may still prove to matter most of all. While the decline in church practice or missionary enthusiasm in France or Ireland is undeniable, there is as yet little evidence to suggest that world wide the strength of Catholicism is in decline and, if the reforms of Vatican II have led to a shaking of the foundations unprecedented for many centuries, they have also contributed to a massive renewal evident above all within the third world.

Catholicism and Gender

Abstract

This article surveys the developing views of gender in Roman Catholic thought and practice. It includes New Testament thought, the era of the Fathers of the Church (AD 200–600), Medieval Latin Christianity, Counter-Reformation Catholicism, and Modern Catholicism through the Second Vatican Council to the pontificate of Benedict XVI.

New Testament Era

Christianity in its New Testament beginnings appeared to offer a gender-inclusive promise of redemption. Both women and men entered the baptismal waters equally, to be freed from the corrupting power of the old Adam and to rise to newness of life in Christ. This vision of an inclusive community of redemption was rooted in the ministry of Jesus and the early Jesus community. Here it was suggested that women and other despised people who suffered from various forms of impurity and subordination are not just included as equals in a new community of redemption, but this new community represented a radical dismantling of the old system of social hierarchy. This vision was expressed in the baptismal formula cited in St. Paul's *Letter of the Galatians* (3:28):

> For as many of you as were baptized into Christ have put on Christ. There is neither Jew nor Greek, there is neither slave nor free, neither male nor female; for you are all one in Christ Jesus

This baptismal theology probably preexisted Paul himself and was taken over by Paul from the Christian community he joined. In its roots in Jewish Christianity, this theology may have suggested a redemptive return to the pregendered humanity before the 'fall' into male and female, an idea found in Philonic Judaism (Hellenistic Judaism as written by Philo Judaeus) expressed in celibate communities of spiritual life, such as the Egyptian Therapeutae (a Jewish contemplative community of the first century). Earlier versions of this theology focused only on the transformation of the gendered pair in redemption. This view is found in several early Christian gospels, such as the *Gospel of the Egyptians*. Here Jesus replies to Salome's question about when redemption will happen by saying, "when you tread on the garment of shame and when the two become one, the male with the female, neither male nor female." Similarly, in the *Gospel of Thomas*, "Jesus said to them, 'when you make the two one and you make the inside as the outside and the outside as the inside, and the above as the below, and when you make the male with the female into a single one, so the male will not be male and the female not be female, then you shall enter the Kingdom'" (22:4-7).

In the context of the early Christian mission where slaves and free persons, Jews and gentiles, mingled in assembled communities, some leaders extended this theology to a three-paired formula of Jew and Greek, slave and free, male and female. It was this three-paired formula that Paul took over in the baptismal theology he cites in Galatians. But Paul did not actually focus on the slave/free or male/female pair. His main interest was in the Jew/Greek dichotomy, or as he put it, "For in Christ Jesus neither circumcision nor uncircumcision is of any avail, but only faith working through love" (Gal. 5:6). Only when a conflict arose in the church in Corinth, which had a constituency that strongly supported gender equality and emancipation from slavery, did Paul take heed of these other social implications and begin to formulate a theology of redemption to curb them.

In his letter to the Corinthians, Paul addresses a number of issues relating to the status of women in the Church. One of these is celibacy. Some women who exercised prophetic roles in the liturgy had embraced celibacy, which they understood as freeing themselves from subordination in the patriarchal household. Paul responds to this by cautioning against celibacy as a temptation to fall into immorality. Despite his own celibacy, Paul advises that almost everyone else should marry and maintain sexual relations, although they might abstain briefly for prayer. Underlying this advice is his belief that redemptive transformation has not yet happened and so the Corinthians cannot act as if they were already in a state of freedom from sin through baptism (I Cor. 7).

Paul then moves to the issue of women covering their heads when they pray and prophesy. He opens this discussion with the assertion of a hierarchical theology of 'orders of creation.' God is the head of Christ, Christ is the head of the male, and the male is head of the female. This hierarchy has not changed for the baptized. So women have no right to remove their head coverings, which symbolize their subordinate status under the male. Moreover woman in herself is not the image of God. The male should not cover his head because he is the image and glory of God, but the women possesses this image only secondarily under the male (I Cor. 11: 7).

Paul then turns to the relation of speaking in tongues to orderly intelligible speech. Because women were not trained in didactic speech and were freed to speak in public only when ecstatic speech was allowed, this argument had the effect of subordinating women's speech to that of male leaders, a consequence that was enforced by the (later added) commandment that "the women should keep silence in the churches for they are not permitted to speak but should be subordinated, even as the law says" (I Cor 14: 34).

Paul's successors in treatises such as Ephesians and Colossians sought to systematize his efforts to shore up social hierarchy in the church by spiritualizing equality in Christ and separating this inward transformation from social relationships. For them the hierarchical relations of the patriarchal family remains intact. This is expressed in commandments, such as "wives, be subject to your husbands," "children, obey your parents in everything, for this is your acceptable duty in the Lord," and "slaves obey your earthly masters in everything, not only while being watched and in order to please them, but wholeheartedly, fearing the Lord" (Col. 3: 18, 20, 22).

But more egalitarian visions of the church did not die out. The conflict between these two views continued into the second century. The deutero-Pauline (secondary Pauline writers, followers of Paul) letter of I Timothy sought to counteract women's claims to public ministry in the church by a patriarchal reading of Genesis I-3. The author asserts that women were created second in the order of creation but were first in sin. Their subjugation, reflecting their secondary place in creation, is redoubled as punishment for their primacy in sin. They may not preach but must keep silence. They will be saved only by accepting this subjugation in marriage, child bearing, and modest, submissive behavior (I Tim. 2:11-15).

But this letter also reveals the existence of alternative views among women in this church who are claiming an active ministry that the author seeks to curb. This alternative is reflected in writings such as the *Acts of Paul and Thecla* in which a converted woman takes the lead in itinerant ministry, resists imperial repression while baptizing herself, and claims Paul's authority as the one who commissions her to 'go and teach the word of God.'

The Patristics Era

Second-century Christianity was diverse and syncretistic. A number of movements, which were later marginalized by Orthodox leaders, advocated withdrawal from marriage and gender equality. Among these was Montanism, led by three prophets, two female, and one male. They saw themselves as possessed by the Paraclete sent by Christ and speaking in the name of the risen Lord. They believed they were living in the last days of world history, prepared for martyrdom, and awaiting the imminent arrival of the redemptive New Jerusalem.

Another expression of radical Christianity was Marcionism. Its founder, Marcion, was a dualist who saw the creator of the world and the giver of the law as the author of an oppressive universe of social hierarchies and violence. The true God of Love has sent his son Jesus into the world to liberate us from the laws of the evil Creator. Redemption gathers a community of equals that overcomes these divisions.

Valentinianism was another variant of radical egalitarian Christianity of the second century. The Valentinian school interpreted the fall of Adam and Eve and redemption in Christ through a story of cosmic devolution from and reintegration back into a higher divine world of divine beings. A female divinity, Sophia, is the mediator between the two worlds, bringing about its fall, but also calling it back into communion with the divine Pleroma. Valentinian communities were led by men and women who were seen as rising above gender division into androgynous unity.

In an early third-century writing influenced by Valentinianism, *The Gospel of Mary*, the risen Christ chooses Mary as his beloved disciple to interpret his message to the other disciples. Andrew and Peter then dispute her authority, but Levi defends her and even suggests that attaining redemptive humanity depends on being able to hear spiritual insight from women. Rather than contending against women, the true Christian should "put on the perfect humanity and preach the gospel, not laying down any rule or law beyond what the Savior said." For these Christians the Savior did not lay down any law subordinating women.

Other theological leaders, Tertullian in North Africa, Irenaeus in Gaul, and Clement and Origen in Alexandria, among others, criticize Marcionite and Valentinian views and establish an orthodoxy that rejects them. Women are eliminated from public ministry in these churches. Although women were recognized as having prophetic inspiration, they were to communicate their visions to the male leaders, not testify in the community assemblies.

By the fourth century the more radical versions of redemptive equality had been mostly defeated. The women who flocked into celibate Christian monastic life in the fourth and fifth centuries mostly accepted their segregation from public ministry and from preaching in the church. Yet the idea continued to linger in monasticism that the female ascetic, by virtue of renouncing marriage and sexuality, was no longer under male domination. A number of women from leading Roman families, such as Marcella, Melania the Elder and her daughter Melania the Younger, Paula and her daughter Eustochium, pioneered prayer and study groups in Rome and later built monastic communities in Jerusalem and Bethlehem.

The leading monastic circle of Cappadocia, led by Basil the Great and his brother Gregory Nyssa, was pioneered by their sister Macrina who turned the family estates into a religious community. Gregory Nyssa saw his sister as his spiritual mentor and wrote his major treatise, *On the Soul and the Resurrection*, as a dialogue with her. She is seen as the embodiment of divine wisdom who leads him through a process of increasing understanding of the journey of the soul from its fall into sin and death into restored glory in communion with God.

In the Latin Church, Augustine emerged as the major theological voice. He sought to reconcile these contradictions between creational patriarchy and redemptive equality in Christ. He recognized that to be redeemed, women must be affirmed as created in the image of God. But he also felt bound by the Pauline dictum of I Corinthians that the male has priority as the image and likeness of God. Augustine's solution was to split the image of God as a gender-neutral soul from woman's nature as female. Women possess the image of God and hence a redeemable soul in their spiritual humanness, but as females they are not the image of God, but rather the image of the body, the subjugated lower creation.

For Augustine, the woman was made subject to the male in the original creation. This subjugation has to do with her role as wife and sexual partner in the production of children. Furthermore, due to Eve's primacy in leading the male to

disobedience to God in Eden, women's original subordination has been worsened into coercive servitude. This subjugation has not been overcome by baptism nor is it lessened by celibacy. Monastic women are still subject to male church authorities. The Christian woman should accept her subordination as both an expression of her original place in creation and punishment for her primacy in sin. This subjugation will be overcome only in heaven when the created order of sex, procreation, mortality, and sin will be swallowed up in redemptive immortality. Only then will women become fully equal with men according to her redemptive merits.

Medieval Christianity

The Latin Middle Ages also saw further denigration of women. This affected the status of women as ordained ministers. The New Testament and Patristic periods understood women as ordained to the deaconate by the same ceremonies by which men were ordained. There is some debate in the twenty-first century whether women were ordained priests and bishops in some communities. This seems to have been the case for groups such as the Montanists and Marcionites. Orthodox Christians sought to deny women the priesthood, but women as ordained deacons continued into the Middle Ages. Some abbesses were ordained deacons. Ordination was understood functionally. A minister was ordained to specific services within particular communities.

In the twelfth to thirteenth centuries, this view was radically changed. Ordination was defined as conferring the specific power to 'confect' the Eucharist and was limited to males only who could exercise this power wherever their superiors assigned them. A renewed misogyny demonized women as 'the cause of our ruin.' Roman law was cited to subjugate all women, and Aristotle's anthropology used to prove that women were inherently defective as human beings.

The Dominican theologian, Thomas Aquinas (1225–74), developed his view of women based on Aristotle. Aristotle believed that the male seed possessed the entire formative power of procreation, while women provided only the 'matter' shaped by the male seed. Every seed could shape a male embryo. Only when the female matter was shaped insufficiently by this seed was a female produced who lacked full humanity, in intellectual capacity, moral will, and physical strength. For Aquinas, following Aristotle, women could not take any leadership role but was by nature under male subjugation.

Aquinas' view of women had implications for his Christology. God's Word had to be incarnated as a male to manifest 'perfect' humanity. It then followed that only males could be ordained priests to represent Christ. Women are not only barred from ordination juridically but are incapable by nature of validly receiving this sacrament. Women also cannot exercise any form of sovereignty in society, such as a ruling monarch, even though women as queens did have such roles in the Medieval world. Aquinas did accept that God might bestow prophetic gifts on women, although he believed they should exercise such powers only privately through male superiors. Yet he did not deny that women might possess personal holiness, at times superior to many men. Like Augustine, he saw women coming into equality with men according to their spiritual merits in heaven.

Yet many women did flourish as spiritual leaders in Medieval Christianity. Although barred from being priests, the Medieval Church continued the early Christian view that women could be prophets. This opened a significant space for women's spiritual gifts and teaching roles in religious communities. Unlike the Patristic era during which few women's actual writings are preserved, the Middle Ages provides us with many scores of women's religious works. A key resource for this existence of women's writings was women's monastic communities that cultivated women's literacy in Latin or the vernacular, possessed scriptoria where manuscripts were copied and libraries where they were preserved.

One of the leading medieval woman writers is abbess Hildegard of Bingen (1098–1179) who was accepted as a prophetess by the highest church authorities, including the Pope.

Hildegard wrote theological, botanical, and medical texts, as well as almost 400 letters, many liturgical songs and musical compositions and poetry, as well as supervising the artistic illumination of her visions. She wrote three major theological works, *Scivias* or 'Know the Way,' the *Book of Life's Merits*, and the *Book of Divine Works*, which lay out her visions of Creation, Fall, and Redemption and its ethical mandates for Christian life.

Hildegard sees the female divine powers of 'Wisdom and Love' (*Sapientia* and *Caritas*) as God's primary agents in shaping the creation of the Earth and guiding humanity after the Fall into redemptive history and its eschatological culmination. Although Hildegard accepts the gender and class hierarchies of her society, she sees those gifted with the prophetic Word, such as herself, as playing key redemptive roles for humanity and the Church.

An important movement for medieval Christian women was the Beguines. These were urban communities of women, mostly middle and working class, who took no permanent vows, were not enclosed in monastic walls, but supported themselves through manual labor, especially in textiles, cared for the poor and the sick, and taught children and women. The Beguines produced a number of leading mystical theologians. Among them are Mechtild of Magdeburg (1210–83) and Hadewijch (thirteenth century).

Mechtild, in her writing, *The Flowing Light of Godhead*, describes her vision of the journey of the soul in its love relation with God the Father and his Son. She joined a Beguine community in her early 20s where she lived for 40 years. In her old age, Mechtild moved to the learned women's monastery of Helfta where she was supported in writing the seventh and last book of her manuscript. Hadewijch was a Flemish Beguine who was a contemporary of Mechtild. In her *Poems in Stanzas*, she writes as a male knight errant pursuing the love of God as her Lady Love; while in her *Visions*, she pursues the love of God as a female soul longing for union with her Beloved.

Another important female mystic is the fourteenth-century English visionary Julian of Norwich (1343-after 1413). When she was 30, Julian had a series of visions of Christ dying on the cross and God's love for us. Retiring to an anchorhold (enclosed cell connected to a parish church), Julian lived the rest of her life meditating and writing on these visions. Notable in Julian's thought is her exploration of the Trinitarian nature

of God as both mother and father. She writes, "in our making God almighty is our kindly father and God all-wisdom is our kindly mother, with the love and goodness of the Holy Spirit."

Although Julian and other Medieval theologians, such as Bernard of Clairvaux, cultivated the feminine image of God as Wisdom, the most important female symbol for the divine is Mariology. Theologically, Mary is not divine, but the representative of the ideal human, but for Catholics she functioned as a divinity, installed in heaven next to her divine Son and mediating between God and humanity. Mariology grew over the two millennia of Catholicism. The New Testament Church made no direct Marian claims, affirming Jesus' virgin birth primarily as a Christological doctrine. Patristic Christianity elaborated the idea of Mary as the New Eve, parallel to Christ as New Adam, Mary's perpetual virginity, her title as Theotokos or Mother of God and the Assumption or belief that she was carried to heaven at death.

Medieval Christianity added the idea of the Immaculate Conception, the belief that Mary was conceived in the womb cleansed of original sin. This was disputed by some theologians, such as Thomas Aquinas, who preferred the view that she was sanctified in the womb later in gestation, but the Franciscans advocated the dating of this to her conception. This doctrine, along with the Assumption, were declared doctrines only in modern times (1854, 1950).

But the Middle Ages saw a great flowering of devotion to Mary. Her feast days proliferated, hundreds of churches were dedicated to her, and the Mary altar became a standard part of every church. Her relics multiplied in numerous shrines, and private devotions, such as the rosary, directed worshippers to pray to her daily. Theologically she was exalted as the embodiment of the unfallen human in its original and perfect state, the appropriate vehicle for God's incarnation, and the Queen of Heaven extending a forgiving hand to unworthy humans. As manifest in modern appearances, such as the Virgin of Guadalupe in Mexico, Mary becomes the central mediator of God's grace.

Counter-Reformation Catholicism

The Reformation era of the sixteenth and seventeenth centuries was in some ways a setback for women. Laws that allowed women membership in guilds and control of property were narrowing. The Protestant Reformation abolished celibacy, while championing the patriarchal family. Women could not be ordained and should not preach. Their sole vocation was that of dutiful wife and mother. Women lost many vocations and roles that had been available through celibate female communities.

In Catholic areas, monastic life for women continued, but the narrowing of women's legal and economic opportunities also happened there. The Catholic Counter-Reformation stressed the strict cloistering of women and resisted the efforts of many creative women of the period, such as Mary Ward in England, who sought to found new noncloistered activist orders with teaching and social roles for women. Women were either to be wives obedient to their husbands or cloistered nuns chanting prayers under the supervision of male church authorities.

A few Catholic humanists, such as Erasmus, championed women's expanded education. The maverick Catholic magician Agrippa von Nettesheim even suggested that women originally were not only spiritually equal to men but also superior to them as representatives of the divine Wisdom of God. He claimed that male domination was recent and expressed, not God's will or female inferiority, but simply male tyranny. But this view conflicted with the trends of the times and would not be heard again for two centuries, when the late-eighteenth-century feminist, Mary Wollstonecraft, championed women's rights in her treatise, *The Vindication of the Rights of Women* (1792). Feminism would not appear among Catholic women until after the Second Vatican Council in the 1960s.

Modern Catholicism

There was virtually no organized Catholic participation in the first wave of American feminism that ran from the Women's Rights Convention in Seneca Falls, New York, in 1848 to the winning of women's suffrage in 1920. The reasons for this lie in several factors; first, the Catholic bishops were vehemently opposed to feminism, associating it with secular modern apostasy to Christian and 'family' values, represented by child labor laws, birth control, the Equal Rights Amendment, divorce, liberalism, and socialism. Many bishops explicitly rejected women's suffrage itself, claiming it would take women out of their proper sphere in the family.

The view of gender that came to prevail in nineteenth- and twentieth-century Catholicism was no longer one that stressed women's inferiority, but rather their complementarity to men. Women were different and even in some cases better than men, but their specific nature lay in their passive auxiliary being. Women were to be 'Marylike' rather than 'Christlike.' They are to represent the church in its subordination to Christ and to masculine leadership. They should not take any such leadership themselves. In these views, Catholicism echoed and put its particular stamp on the romantic views of gender complementarity common to the period.

The conflict between official Catholicism and feminist advocacy for women has developed in the Catholic community in the post–Vatican II era. Vatican II itself largely ignored women. Women, even women religious, were absent from the delegates to the Council. Protest about women's absence by Cardinal Leon-Joseph Suenens in 1962 brought a slight change. A few women religious and lay women were allowed as 'auditors' without vote in the later sessions of the Council. Three even served on commissions that drafted the final Council statements, specifically those on 'The Church in the Modern World' and on the 'Apostolate of the Laity.'

The final documents of the Council have a few concessions to women's new role in work and legal equality in modern society. It is said that women are claiming a new equity for themselves before the law and in fact, and the participation of women in cultural life should be acknowledged and supported by the Church. These statements are echoed in Pope John XXIII's encyclical *Pacem in Terris* (1963). Here it is said that "women are becoming ever more conscious of their human dignity. They will not tolerate being used as mere material

instruments, but demand rights befitting a human person in both domestic and in public life" (Sec. 41).

These concessions to women's role in public society did not include changes in the life of the Church itself, in terms of women's ordination or in teachings on sexuality and reproduction. Both of these issues were being challenged in the 1960s. Mainline Protestant churches in Western Europe and North America had begun to ordain women in increasing numbers in the 1960s. In 1976, the American Episcopal Church endorsed women's ordination, a change that brought women into the priesthood in a tradition closely related to Catholicism.

The Roman Magisterium responded to these developments with an encyclical that same year insisting that women could not be ordained because women lack the capacity to 'image Christ.' Maleness and the representation of Christ as a male were thus identified in a way that many Catholics came to see as questionable. Some theologians, such as the eminent Karl Rahner, even suggested that such literalness about Christ's maleness as necessary for his sacramental representation is heretical. Far from ending the discussion, support groups for women's ordination have grown among Catholics since 1975 in Europe and North America.

In 1975, U.S. Catholics convened the first Women's Ordination Convention in Detroit. From this conference emerged the Women's Ordination Conference that works on this issue in Roman Catholicism nationwide. In 1996, the Women's Ordination Conference Worldwide was founded at the First Women's Synod in Gmuden, Austria, to promote women's ordination, particularly in the Catholic church, worldwide. This group is closely connected with the U.S. Women's Ordination Conference and has held several global meetings.

Another stage of this challenge developed in 2002 when seven women from Germany, Austria, and the United States were ordained priests on a boat in the Danube River in Austria by several male Catholic bishops. Several of these women were subsequently ordained bishops by these Catholic bishops. They, in turn, have continued to ordain women deacons, priests, and bishops, creating a new movement called Roman Catholic WomenPriests. By 2011, there were five women bishops, 65 women priests, and 13 women deacons in the United States and one bishop, seven priests, and one deacon in Canada.

The movement is organized into a number of administrative districts in the two countries that oversee theological education, preparation for ministry, and ordination of women seeking priesthood. These women priests in turn have created a variety of ministries, worshipping communities, retreat centers, and chaplaincies in prisons, hospitals, and schools. This movement has been strongly condemned and declared excommunicated several times by the Vatican. But this has not deterred their expansion and their continued claim that they are validly ordained as priests in the Catholic tradition.

Another area of contention among Catholics has been the traditional teaching that sex (allowable within marriage alone) is primarily for procreation and cannot be separated from its procreational potential. Birth control (other than the rhythm method) is forbidden. As moral theologians and ordinary lay Catholics began increasingly to question these teachings, and called for this issue to be discussed in the Second Vatican Council, Pope Paul VI decided to steer this discussion away from the Council by convening a special commission to study it. The commission meet from 1964 to 1967. Its membership expanded, and it came to include three married couples from the Catholic Family Movement. One of these couples, Pat and Patty Crowley from the United States, collected documentation from members of the Family Movement, which testified to the anxiety caused by the rhythm method and its unreliability as a method of family planning.

Members of the Commission were deeply moved by these findings, and they voted to change the teachings of the Church to one that accepted all medically approved methods of birth control within the context of committed, child-raising married families. But this official report, which was supported by the vast majority of the Commission, was rejected by Pope Paul VI after he had been advised by a few dissenters that such a change would threaten the Church's claim to infallible teaching. The reaffirmation of the anti-birth control teachings in the papal encyclical *Humanae Vitae* (1968) created a storm of protest throughout the Church. Many priests and moral theologians openly dissented. Many lay Catholics simply have chosen to ignore Church teaching on this subject. Yet the Vatican under Popes John Paul II and Benedict XVI have continued to insist on the inerrancy of this teaching, deepening the conflict between the laity and the Magisterium of the Catholic Church on the question of contraception.

Realizing the deeply conflicted state of relations between the official church and women, the American Catholic bishops voted in the early 1980s to engage in an official dialogue between the bishops and the Women's Ordination Conference. After several years of meetings, the bishops who were members of the dialogue persuaded the other bishops that they should undertake a pastoral letter on women in the Church. They conducted a series of listening sessions with Catholic women across the United States to hear their issues. They then drafted an epistle that declared that men and women should be partners in the family, society, and the church. This epistle condemned sexism as a 'sin.'

But the Vatican intervened in the process of drafting this letter, demanding the condemnation of birth control and women's ordination as a part of the letter, and that the model of relationship between men and women should be one of complementarity, not partnership. The result of these interventions was a decision by the American bishops to table the letter, rather than issue a document that was likely to worsen, rather than improve, relations with women in the church.

These conflicts between teaching and practices of the Catholic Church and the growing consciousness of their rights to equality among Catholic women (and their male supporters) is by no means limited to North America. Catholic feminist theological networks have grown in Western Europe, as well as in Latin America, Asia, and Africa. With the growing lack of adequate ministry by celibate male priests throughout the world, more and more of the ministerial work in Catholic parishes and chaplaincies is being done by theologically trained laity, especially by women.

Thus, the conflict between the Catholic hierarchy and women, exacerbated by the reactionary policies of Popes John Paul II and Benedict XVI that undermined the reforming hopes of the Second Vatican Council, shows no signs of improving in the second decade of the twenty-first century. The issues go far beyond the inclusion of a few token women in clerical office.

They call for a fundamental rethinking of ancient traditions rooted in male ecclesial patriarchy and a view of femaleness and sexuality as expressions of inferiority and sin to be distanced from sacramental office.

A thoroughgoing revision of these patterns any time soon in official teachings is unlikely. Since women who claim more egalitarian views about themselves and their rights to decide about their own bodies show no signs of disappearing in large numbers from the Catholic Church worldwide, this conflict will continue to be present for the foreseeable future as a deep schism concerning the meaning of gender identity in Catholicism.

Abstract

Raymond B. Cattell was born on 20 March 1905 in Staffordshire, England. He was educated in England, where he began his academic career in chemistry but eventually moved into psychology. He received his Ph.D. in 1929. Over a long and very productive career, Cattell managed to keep one foot in the theory of behavior and the other well-grounded in empirical research to test and extend his theories. His approach to the study of behavior was highly quantitative and dominated by the model of factor analysis. Cattell applied his methods to the domain of personality, broadly defined, and made salient contributions to the measurement and modeling of human abilities, temperament, motivation, learning, and the nature of developmental change. He pioneered the study of intraindividual variability in personality, both methodologically and substantively. Cattell was the central force in organizing the Society of Multivariate Experimental Psychology, in founding its journal *Multivariate Behavioral Research*, and in producing the first edition of *The Handbook of Multivariate Experimental Psychology*. He died on 2 February 1998 at the age of 92.

In describing the psychologist Raymond Bernard Cattell's comprehensive research program, Child, in a single sentence, gave an amazingly complete and accurate description: 'His major concern was to map out an integrated theory of human intellectual, temperamental and motivational characteristics within the context of hereditary and environmental influences using multivariate methods of analysis' (Child, 1998, p. 356). In trying to convey the sweep of Cattell's theoretical and empirical work Goldberg (1968) referred to him as 'psychology's master strategist' (p. 617). Indeed, the sheer audacity of venturing into so many major research areas during one career is unlikely to be seen again for some time.

Raymond B. Cattell was born on 20 March 1905 in Staffordshire, England. He was raised in Devon, near the town of Torquay. Cattell began his academic career in chemistry at University College, London and received his Bachelor of Science degree with first class honors in 1924. Drawn to the study of psychology, Cattell began work on a doctorate at King's College, also in 1924. After completing his Ph.D. in 1929, Cattell did some teaching at University College, Exeter before becoming Director of the School Psychological Services and Clinic at Leicester in 1932.

In 1937, E. L. Thorndike invited Cattell to come for a year to Columbia University as a research associate. Subsequently, he also spent brief periods at Clark, Harvard, and Duke universities. During his time at Harvard, Cattell began seriously to develop the methodology for intensively studying the single case (P-technique factor analysis) in which he remained interested throughout his career. Cattell acknowledges that with his ' ... office ... having been next door to Gordon Allport's, the latter may also have played an initiating part' but goes on to lament that although Allport, too, was ' ... in pursuit of uniqueness of personality ... ' he had ' ... some unreadiness to come to grips with statistical models' (Cattell, 1984, p. 141). Exhibiting a certain disdain for those who refused to use 'proper' methods, no matter how celebrated their status, was one of Cattell's stable characteristics.

Cattell worked for a time during the latter years of World War II in the Adjutant General's Office. In 1945 he became a research professor at the University of Illinois in Urbana-Champaign and remained there until 1973 when, in part due to age restrictions then in force, he retired. He moved on to the University of Hawaii where he maintained a special appointment for a few years. When that appointment ended, Cattell stayed in Honolulu and continued to work informally with several younger colleagues and to publish an occasional paper. One of his last publications (McArdle and Cattell, 1994) brought to a close his 50-year affair (Cattell, 1944) with the beguiling concepts of 'parallel proportional profiles' and 'confactor rotation,' more of which will be said later.

By far the longest and most productive portion of Cattell's scientific career occurred while he was Director of the Laboratory of Personality Assessment and Group Behavior (later the Laboratory for Personality Analysis) at the University of Illinois. It was from this setting that his influence on the development of the science of psychology hit its maximum. The sheer number of big ideas and level of productivity in following them up during those years are remarkable. His success in claiming his 'fair' share of CPU time on the Illiac, the university's automatic computer, was legendary. Although by today's standards, its capacity was meager, at the time the Illiac allowed Cattell to do large factor analyses in weeks and months that would otherwise have taken years.

Contributions to the Methods and the Substance of Psychology

Raymond B. Cattell is an exemplar of a class of psychological researchers who were heavily invested in the application of quantitative models to the study of behavior. Also included were the likes of Cyril Burt, Hans J. Eysenck, J. P. Guilford, Charles Spearman, Godfrey Thompson, and L. L. Thurstone. Let it be said openly that this is not a list of like-minded individuals who necessarily had more in common than not. Rather, it is a list of important contributors to the development of psychology as a science who relied substantially on the models and methods of factor analysis in their empirical research pursuits. In both strategy and tactics, they differed from each other in the use of factor analytic methods.

Because of Cattell's heavy reliance on factor analysis, it is not possible to separate the substance from the methods. In fact, in an earlier review of Cattell's research program in *Theories of Personality* (Hall and Lindzey, 1978), the chapter heading is 'Cattell's Factor Theory.' Therefore, a discussion of his work can be usefully begun with a methodological introduction.

At the heart of Cattell's research program lay the basic equation of the common factor model. Cattell referred to it as the factor specification equation and wrote it as:

$$a_{ji} = b_{j1} \cdot f_{1i} + b_{j2} \cdot f_{2i} + \cdots + b_{jk} \cdot f_{ki} + u_{ji}$$

where a_{ji} is a score for person i on behavior (or act) a_j, and fqi ($q = 1, 2, \ldots, k$) represent the ith person's endowments or scores on the k common factors, the b_{jq} ($q = 1, 2, \ldots, k$) are weights (factor loadings) that specify the amount to which any individual's score on the qth factor contributes to (in Cattell's theoretical framework, *determines*) his score on variable a_j, and u_{ji} is a contribution to a_{ji} that is unique to both the behavior and the individual. The u_{ji} terms include both errors of measurement and portions of the observed score that are reliably measured, but fall outside the purview of the common factors defining the interrelations of a given set of variables.

The b_{jq} values, which Cattell referred to as situational indices (later, behavioral indices), brought the situation and the individual's traits into the same equation so that both individual and situational information could be used to predict behavior. Suppose, for example, a given individual had a very high endowment on the factor Cattell labeled Exvia, which was similar in nature to the individual differences dimension called Extraversion in many personality research and theory contexts. If, on the one hand, the b_j for Exvia with respect to performance of a given a_j was small, then that high level of Exvia had little or no bearing on that person's a_j score. On the other hand, however, if b_j for Exvia on performance of a given a_j was large, then that high level of Exvia had major influence in determining that person's a_j. By contrast, for the person with a near zero level of Exvia, little would be contributed to their performance on a_j by the Exvia factor even if the b_j for Exvia was large, because the product $b_{j,exvia} \cdot f_{exvia,i}$ would be close to zero.

This factor specification equation is thus a 'working model' of the individual differences orientation in that the differing amounts of the latent attributes possessed by different people (variation in the f_q) are 'converted' into differences in their scores on the observed variables (variation in the a_j). By knowing the amounts of a person's trait endowments and the magnitude of the contribution the traits made to manifest variables, one could predict an individual's scores on the manifest variables, that is, behavior.

Within that framework, the scientific agenda is rather clear: define the latent factors as clearly as possible, construct tests to measure them accurately, and develop empirically based estimates of the b values for the manifest variables, the a_j, of interest. Then one has made the prediction objective of science reachable and can also elaborate an explanatory system as well by detailing more and more regarding the nature of the factors (e.g., see how the factors behave across different media of observation and how stable they are across time, examine their genetic and environmental variance contributions, plot their age changes, etc.). Attacking these several objectives was a major part of Cattell's research program.

Thus, despite knowing the adaptations in the methods of the physical sciences had to be made in studying behavior, Cattell's methodological approach showed a deep reliance on fundamental principles of physical science. He believed that factors were causal influences on observable variables and that, in analytical work, when the factors had been properly rotated to their 'causal influence' identities, the factor loadings (the b_j values in the specification equation) would be proportional for a given set of behaviors (the a_j values in the specification equation) across different samples. This represented an explicit commitment to a fundamental objective of scientific research: the identification of relationships that remain *invariant* under different transformations. In his context, Cattell formalized this notion in the terms 'parallel proportional profiles' (the results) and 'confactor rotation' (the method) mentioned earlier. Along the way, he worked on the development of methods for assessing the similarity of factor loading patterns so that one could render some judgment about factorial invariance even without reaching the ideal parallel proportional profiles.

Cattell was also firmly committed to the principles of rigorous, quantitative measurement and scaling and once presented, with characteristic lack of modesty, a proposed more basic set of concepts (Cattell, 1964) to replace the prevailing notions of reliability and validity. In so doing, he again challenged the status quo regarding the role of item homogeneity in evaluating the quality of measuring instruments.

Cattell placed a strict reliance on mathematical representations of phenomena of interest although, in his case, this amounted generally to using some variant of the common factor model. His insistence on the introduction of rigor into the definition of psychological concepts left its mark in a number of ways. He argued that ambiguity and confusion about concepts could be reduced by discarding as many of those in vogue as possible, discovering and defining new ones, and giving them new names to mark their unique status. In the process, he delivered such labels as 'cortertia' (cortical alertness) and 'threctia' (threat reactivity) to identify major individual differences in dimensions of personality.

A monograph on real-base, true zero scaling (Cattell, 1972) illustrates the concern he held for fundamental issues of scaling, the commitment and energy with which he would attack a problem, provide a solution, and advance it for discussion and debate. Debate, however, was not always the reaction evoked by his proposals.

In addition to this strong analysis and modeling orientation, Cattell's research program was buttressed by several other key attributes. Where others might carve up the study of behavior to identify more clearly a piece for themselves in the broader scheme, Cattell did so as away of more systematically approaching the whole. Much of his work was organized around the tripartite division of abilities, temperament, and motivation. But he enriched this classical triumvirate by distinguishing between surface and source traits, estimating heritability coefficients, and incorporating concepts of psychological states, learning theory, and situational influences. He introduced the multiple abstract variance analysis (MAVA) design to incorporate different family configurations into the estimation of heritability coefficients and in the design of correlational studies he saw not one, but six important ways to interrelate variables, persons, and occasions of

measurement. He systematized the latter in a heuristic often referred to as the 'data box' or covariation chart (Cattell, 1952) which is still frequently encountered in the literature.

As an example of his capacity for orderly abstraction and the willingness and ease with which he would think 'big,' Cattell was not satisfied to name and report the results of his many factor analyses. Instead, he proposed the development of a Universal Index (U. I.) of factors, the first 15 of which (U. I. 1 through U. I. 15) were to be reserved for what he considered to be the well-established human ability factors. He then proceeded to assign the next 17 numbers (U. I. 16 through U. I. 32) for factors based on objective tests on which he had published. He invited further contributions to this indexing system but, as one might expect from even a passing acquaintance with human nature, one person's proposal for a Universal Index is hardly likely to be adopted readily by others.

In addition to a frequently observed trait of successful research scientists – a desire to be first and to receive credit for it – Cattell was gifted with a high level of intelligence and capacity for abstract thought. He made up many of the items for the Culture Fair Intelligence tests (Cattell, 1954) himself; took delight in the rapidity with which he could solve items from 'would be' intelligence test item writers and, in return, relished 'stumping' them with a recently written item or two of his own.

The levels of abstraction with which Cattell felt quite comfortable were in many cases a far remove from data. For example, second-order factor analyses (factor analyzing the intercorrelations of factors) were routine in his laboratory. Third-order factor analyses, while not routine, were completed on several occasions to which published papers attest. Along the way, at least one fourth-order factor analysis was conducted.

Cattell was not inclined to be tolerant of others' lack of knowledge of his system. Those who worked in his laboratory were apt to be rebuffed when they would occasionally suggest ways by which he might strengthen the bonds of communication with his readers. 'Let them go and read my 1957 book' (Cattell, 1957), was the reply heard on more than one occasion to the suggestion that a little more detail might be helpful to the reader. Nor, as was already mentioned, was he kindly diposed toward those he felt were not using the multivariate tools of the trade wisely.

Cattell was an avid reader (and writer) of poetry and also enjoyed biographies from which he enriched his own writing. His enormous legacy of books, chapters, and articles, numbering well over 500 publications, exhibit many examples of his caring about the craft of writing as well as the ideas being written about. He would search for just the right word or turn of phrase – and did so amazingly quickly! When he was well into his eighties the author once asked him in what areas of his intellectual functioning he could detect losses. He responded that he didn't act on visual input as rapidly as he used to when, for instance, driving his automobile. (This was true!) But, he very quickly added, he could still retrieve adjectives, etc., quite handily when he was writing and he was very pleased about it. Some of his 'classic' remarks, many of which are buried in footnotes, will likely go unheeded by the future generations, and that will be a stylistic as well as a substantive loss. For example, his characterization of the hyperplane as 'the footprint of a causal influence' or his accusation that by developing and making widely available the by then nearly ubiquitous orthogonal analytic rotation program, Varimax, Henry Kaiser had 'put opium on the market,' are illustrative.

Cattell's deep reliance on factor analysis was symptomatic of his belief that the workings of variables should be examined with as little interference as possible from the observer. The methods of factor analysis could then be used to tease out the key patterns of relationships. As any craftsman, Cattell felt strongly about having access to proper tools and worked to evolve factor analytic methods during the length of his career. He did this both by formalizing design with the presentation of the covariation chart or 'data box' and by restlessly pushing technological developments. The ever present need for faster, more efficient methods for conducting factor analysis if his research goals were to be realized, directly resulted in software applications such as Maxplane, Procrustes, and Rotoplot to facilitate rotation of factors to a final solution. The Rotoplot program, for instance, displayed the pairwise factor (actually, reference vector) plots on an oscilloscope and filmed them by 35 mm camera mounted on the oscilloscope. As soon as the film strip could be processed, Cattell would project the plots on his office wall and write down the tangents of the angles of rotation for another run, urgently trying to achieve 'maximum simple structure' so that factors could be interpreted and the article written and submitted. At the time that Rotoplot was invented, others who were doing graphical rotation of factors were having to have each pairwise plot rendered by triangle and T-square.

Bridging Psychology's Past and its Future

Cattell and his research program represent an important bridge between psychology's past and its future. While he was alive, Cattell was a personal, as well as scientific link to the psychology's past. On occasion, he would tell of conversations (sometimes, encounters) with the likes of Burt, Fisher, Pearson, and Spearman. Although he was not a student of Thurstone, he seized on the tool of multiple factor analysis which Thurstone was so instrumental in bringing to psychologists and future refined it to his own ends. At the same time, his zeal in promoting, and passing along to future generations of researchers not only his substantive findings but also the methods that he thought were appropriate and necessary for psychological research, forged important links to the future. He was a prime mover in establishing the Society of Multivariate Experimental Psychology (SMEP) and the founding of the society's journal, *Multivariate Behavioral Research* (MBR). He helped to launch MBR in 1966 with a provocative lead article entitled 'Multivariate Behavioral Research and the Integrative Challenge,' in which he summarized his own version of the two general traditions of psychological research – the experimental and the individual differences traditions – and pointed out the directions for future research that would elevate the study of behavior to new levels of competence. In that same year the first edition of the *Handbook of Multivariate Experimental Psychology*, for which Cattell was both the editor and the major contributor, was published. A second edition followed 22 years later (Nesselroade and Cattell, 1988).

McArdle (1984) credited Cattell with having a profound effect on the development of what is now referred to generally as 'structural modeling' the fitting of quantitative models to covariance matrices (and occasionally the associated arithmetic means, as well), which has grown to enormous proportion in current day psychological research. This connection reinforces the amazingly productive service Cattell extracted from the factor analytic model. Cattell's empirical and theoretical work, as no one else's, has helped to clarify the distinction between latent and manifest variables and the key properties of both.

The contributions that Cattell made both substantively and methodologically were many. Here, we have only touched on some ofthe major ones. He developed and presented one of the most systematic and encompassing theories of personality that psychology has ever seen. Along the way, he introduced a large number of methodological innovations, some of which have made their way into today's behavioral science argot with an ease that today gives no hint of Cattell's pioneering contribution. The 'scree test,' 'Procrustes' rotation, and 'P-technique' come readily to mind.

The theory of fluid and crystallized intelligence, on which Cattell collaborated closely with Horn (Horn and Cattell, 1966) remains very much in currency today as far as so-called psychometrically oriented models of cognition are concerned. The apparently different age gradients of these two kinds of abilities has helped to stimulate thinking not only about the complexity of the organism and the nature of its development across the lifespan (e.g., Baltesm, 1987), but also about the need to consider what level of aggregation of variables is optimal for a given purpose.

Despite Cattell's strong investment in the study of human abilities (Cattell, 1971), he did not neglect the temperament and motivation components of his research program. For example, the fruits of his efforts to measure temperament by questionnaire, especially, are evident today in the continuing usage of the High School Personality Questionnaire (HSPQ) and the 16 Personality Factor questionnaire (16PF). Some of the work of which Cattell was most proud and for which he had the highest hopes sprang from his contributions to the study of motivation. His concept of the dynamic calculus, which was an attempt to write a systematic prediction equation for behavior that included trait, state, and dynamic aspects was refined into what he came to call structured learning theory. In the author's view, this was a key contribution in Cattell's own evaluation of his scientific legacy.

Many of the individuals who received their scientific training in Cattell's laboratory are still active and productive today. They, in turn, are passing on to their students the concepts of the data box, fluid and crystallized intelligence, covariation designs, factorial invariance, states versus traits, etc.

Despite the comprehensive perspective, the numerous insights and innovations, and the sheer bulk of his scholarly output, which spanned parts of eight different decades, Raymond B. Cattell's place in the history of psychology will not be identified without controversy for the foreseeable future. A lifetime achievement award for his contributions to psychology to be given by the American Psychological Foundation was announced in early 1997. Although Cattell had never taken kindly to the science 'establishment,' he had reached a point in his journey where such a high level of recognition for his scientific work meant something to him. But it was not to be. Some of his more philosophical, provocative writings having to do with the roles in our society of genetics, evolution, and public policy had generated bitter and sufficient resentment that, after some 'negotiating,' the award was withdrawn prior to the 1997 annual meeting of the American Psychological Association in Chicago, where it was to have been given. Cattell died the following 2 February at the age of 92.

Abstract

This article examines the history of causal research traditions in the social sciences. We identify two major bases for the methods and logic of causal analysis in the social sciences – experimental designs and statistical methods – and discuss the developments in these two correlated research traditions, especially the implications of these developments for the social sciences. While the focus of our discussion is on the developments in western societies, we also briefly review prominent features of causal analysis in the social sciences in non-western societies.

History of Causal Analysis in the Social Sciences

The emergence of causal analysis in the social sciences coincided with the emergence of social science disciplines in the West in the late nineteenth and early twentieth centuries. These disciplines established themselves as university departments and sought to distinguish themselves from natural sciences and humanities that had enjoyed a much longer history in academic research. The distinguishing feature of these social sciences, in particular sociology, has been to understand the causal role of society. Put differently, social scientists want to understand the effect of environment on human behavior. Following centuries-old nature-nurture debate, social scientists intend to distinguish the role of environment from heredity. Since the emergence of social sciences, causal analysis has matured to a recent stage where researchers moved beyond the mere consideration of observables to the analysis of counterfactuals (see Morgan and Winship, 2007).

For the American sociologist Albion Small (1898; 11 May 1854–24 March 1926), the first two of the three phases of social science research, embodied in what he called the 'essential methodological processes,' are elementary analysis, which is descriptive of individual parts or variables of a phenomenon, and causal analysis, which is what we know today as analysis of causal mechanisms. In quantitative social sciences, we still practice these two stages of research today in that order. We further identify two major sources for the methods and logic of causal analysis in the social sciences – experimental designs and statistical methods. The evolutions of these foci have been correlated processes. Note that because of space constraints, we cannot go into the details of other causal research traditions, notably John Stuart Mill's (1883; 20 May 1806–8 May 1873) configurational type of analysis of causality and its contemporary refinements and advances, especially in Charles Ragin's (1987) and his later works in the twenty-first century. In the following sections, we briefly review the two influential sources of causal analysis in the social sciences, namely experiments and statistical analysis.

Randomization, Experimentation, and Social Science Research

Two books on social science research methods that have been considered as modern classics and that have been the standard texts in many graduate-level social science research methods course are Donald Campbell and Julian Stanley's (1963) *Experimental and Quasi-Experimental Designs for Research* and Thomas Cook and Donald Campbell's (1979) *Quasi-Experimentation: Design & Analysis Issues for Field Settings*. A chief difficulty for causal analysis is spuriousness or the effect of confounding variables. Luminaries in both Europe and America in the likes of Small, Emile Durkheim, and Karl Pearson already knew long ago what every social science graduate student is taught today that the specter of spuriousness could only be truly eliminated either by randomization of observations or by a method that somehow resembles or simulates the randomization process. Campbell and Stanley (1963) discuss various types of true and quasi-experimental designs, some of which originated in the early twentieth century, distinguish between internal and external validity of these designs, and warn researchers against various threats to internal validity including history, maturation, testing, instrumentation, statistical regression, selection of subjects, experimental mortality, selection–maturation interaction, and John Henry effect, and to external validity including reactive or interaction effect of testing, interaction effects of selection biases and the experimental variable, reaction effects of experimental arrangements, and multiple treatment interference.

What separates true experimental designs from quasi-experimental designs is the application of randomization, the process that randomly assigns research subjects to treatment versus control groups to allow the understanding as well as the analysis of true causal effects. However, as is well known, randomization in the social sciences is rarely practical or even possible. Samuel Stouffer (1950; 6 June 1900–24 August 1960) emphasized quasi-experiments – experiments that do not apply random assignments for comparison to make inferences about treatment-induced changes but otherwise resemble true experiments. Cook and Campbell's (1979) book reviews some preexperimental and experimental designs but nevertheless focuses on quasi-experimental designs that control many of the validity threats, often drawing on examples from psychology and educational research.

There are other variations of true experiments. One type that was developed in the twentieth century but has received more recent attention is field experiments, which recruit subjects in the field instead of in classrooms or into laboratory settings

although still allowing randomization. Arguing the 'controlled' environment of a laboratory can be artificial, Glenn Harrison and John List (2004) review six criteria that can serve to determine the field context of an experiment: the nature of the subject pool, the nature of information brought to the task by the subjects, the nature of the community, the nature of the task, the nature of stakes, and the environment the subjects operate in.

A special type of quasi-experiments has received a lot of academic and applied attention recently is natural experiment even though the most famous early example is the 1854 Broad Street cholera outbreak in London. Obviously, natural experiments do not have random assignments of subjects. However, they are useful in that there is often a clearly defined and large change in the treatment or exposure occurring to a clearly defined population or subpopulation, with no change in the treatment or exposure for another population or subpopulation. Many good examples of natural experiments come from economic or socioeconomic research. This is an increasingly popular method in the social sciences (for a complete review, see Dunning, 2008).

Statistical Analysis of Causality and Social Science Research

Early statisticians were deeply interested in the analysis of experimental data. Noted statisticians who made fundamental contributions, directly or indirectly, to statistical causal analysis include Ronald Fisher, Jerzy Neyman, Karl Pearson, and George Udny Yule, among others. Fisher's contribution to the design and statistical analysis of experiments is particularly fundamental, proposing the principles of design of experiments and analysis of variance of experimental data. His research culminated in two books (Fisher, 1925, 1935; 17 February 1890–29 July 1962), both of which were standard references for decades to come. Separately, Neyman (1923; 16 April 1894–5 August 1981) was concerned with analyzing experiments with statistical and probability theory as well. Together with Egon Pearson, Neyman also contributed to hypothesis testing in statistics, resulting in what we know as Neyman–Pearson hypothesis testing today and the Neyman–Pearson lemma paved the foundation for hypothesis testing practices up to this day.

The developments have been swift in the past few decades for statistical causal analytic methods in the social sciences. Major developments are represented in the research on structural equation modeling, matching analysis, and more generally, counterfactual causal modeling. Drawing on Sewall Wright's (1920) early work on path analysis in biology, simultaneous equation models in economics (Haavelmo, 1943), and factor analysis in psychology (Spearman, 1904), Karl Jöreskog (1973), James Keesling (1972), and David Wiley (1973) developed a comprehensive analysis system for causal analysis structural equation models with latent variables. The analytic framework became popular with the advances of computer programs, initially LISREL, and later on EQS, Amos, and MPlus. Today, virtually all major statistical software packages contain a module for structural equation modeling, in particular R, SAS, and Stata. The structural equation modeling framework allows causal analysis among not just observed variables but also unobserved, latent variables. The framework may also have some effects on uniting social scientists from different disciplines with a common analytic interest. This analytic approach allows not just a formal way of understanding causal chains but reciprocal causation as well. More importantly, it recognizes that our measurement is never perfect and that it contains measurement error, which can be properly modeled in structural equation modeling. Kenneth Bollen's (1989) book, together with other treatments, has helped make the method more accessible for social science researchers. Also see Judea Pearl's (2009, 2010) treatment of causality in this and related approaches.

A serious challenge to making causal inference is the presence of potential confounding factors when random assignment is absent. Observational studies are situations that lack randomization. Matching, or matched sampling, is a method for reducing bias and for more properly estimating treatment effects (Rubin, 1974; Rosenbaum and Rubin, 1983). Propensity score matching is a prominent matching method that uses observed variables to predict the probability of experiencing the event to create a 'counterfactual' group for making a more proper causal inference. The propensity score matching method has become very popular in the social sciences in recent years, and is implemented in major statistical software packages including R, SAS, Stata, and SPSS. For a notable recent assessment of the method applied in medical research, see Peter Austin (2009).

The essence of propensity score matching is to create a sample of cases that did not experience treatment but that are statistically equivalent, in all other aspects, to members of the treatment group. The procedure obtains a factual–counterfactual matched sample with which treatment effects can be estimated. One reason for the popularity enjoyed by propensity score matching today is because matching on the score is as good as matching on the configuration of all the observed variables involved in the matching (Rosenbaum and Rubin, 1983). Fundamental to this method is the assumption that the nonrandom assignment process is exogenous to the outcome distribution process, an assumption that Donald Rubin (1973) uses. Put differently, the assumption can be viewed as whether assignment to treatment is a self-selection process related to the expected outcome. James Heckman (2005) questions this assumption and proposes a control function approach that explicitly models the relation between the unobserved variable(s) in the outcome and selection equations by modeling the correlated errors in the two equations. Heckman's treatment relaxes the assumption and can be useful when the assumption is violated, thus enabling the researcher to estimate treatment effects when self-selectivity exists. For a comprehensive discussion of counterfactuals and causal modeling, see Stephen Morgan and Christopher Winship (2007). Morgan and Winship have a second edition of the book in press.

Causal Research in Non-western Societies

From the discussion above it is obvious that causal analysis in the social sciences has been entirely developed in the West. The development of the social sciences in non-western societies typically followed the western model. In East Asia, social sciences first developed in Japan, with their roots formed in the Meiji period when the country was open to new ideas from the outside. For example, sociology was introduced to Japan by

Ernest Francisco Fenollosa who gave lectures on the topic at Tokyo Imperial University in 1878 (Shoji, 1996). Accordingly, theoretical and methodological concerns in the social sciences there followed the western model. In China, the development of social sciences was also heavily influenced by the West even though drawing conclusions from social observations can be traced to early thinkers such as Confucius and Lao Tzu. Serious concerns with causal analysis primarily follow the western tradition (see Peng, 2011).

Russian social sciences of the late nineteenth and early twentieth century in prerevolutionary Russia developed closely with the West European tradition of social–economic surveys (*zemskaya statistika*) conducted by elective district councils (*zemstvo*). Further development of this tradition was halted after early 1930s during Stalin's rule, when sociology was claimed to be ''bourgeois pseudo-science.' The revival of sociology in the Soviet Union began during Khrushchev's era from the late 1950s to the early 1960s. The renewal of sociological research led to noticeable advances in methodology of social sciences with influences from both the western tradition and relevant developments in East European social sciences. In particular, the Polish sociologist Stefan Nowak's (1960, 1977) idea of statistical interpretation of types of causal relations in social sciences is worth mentioning. He introduced a typology of causal relations for dichotomic attributes (e.g., general vs conditional, positive vs negative). The typology enabled one to derive statistical relationships corresponding to each type of causal relations for elementary cases.

A version of information-based approach to causal analysis was developed in 1970s by Igor N. Taganov (1977). This is an early attempt to use Markov-chain-based causal reasoning in Soviet social sciences although it has never been widely applied. Soviet/Russian logician Victor K. Finn (1983) developed a formal JSM method of plausible reasoning (named after J.S. Mill) based on multivalent logic and intended for automatic generation and testing of hypotheses. With its foundation in mathematical logic, the method synthesizes the procedures of induction, constructive abduction (in the Piercian sense), and analogical reasoning and can be applied to qualitative social science data for identifying underlying causal structures (Finn, 1983). In his 1997 book coauthored with K.V. Khvostova, *Problems of Historical Knowledge in the Light of Contemporary Multidisciplinary Research* and other publications, Finn describes the procedures of causal hypotheses generation from data consisting of qualitative empirical information on objects and their properties in order to produce a knowledge base comprising explanatory and causal propositions inferred from propositions about the properties of objects. A software implementation for causal analysis (based mostly on 'direct method of agreement' by J.S. Mill) has been successfully applied in different disciplines including sociology, paleography, toxicology, and others. When compared with comparative methods such as Charles Ragin's QCA (Ragin, 1987), this JSM method has the benefit of implementing a rule of 'ban on counterexamples' (Kuchenkova and Tatarova, 2013).

Readers interested in an up-to-date treatment of methods for causal research in the social sciences are referred to the handbook edited by Stephen Morgan (2013), which also includes a chapter on the history of causal analysis in the social sciences.

Abstract

This article explains the connection between counterfactual reasoning and the Fundamental Problem of Causal Inference. The Neyman–Rubin causal model is introduced, as the potential outcome framework on which it is based makes explicit the counterfactual nature of causal inference. The definition of average causal effects and prima facie average causal effects reveals the sources of bias for causal estimates in observational studies Discussion is also given to 'empty' counterfactuals that arise when unalterable attributes of units are treated as if they were treatments in experiments.

The term 'counterfactual conditional' is used in logical analyses to refer to any expression of the general form: "If A were the case then B would be the case." In this usage, A is usually false or untrue in the world so that A is 'contrary to fact' or counterfactual. Examples abound. "If kangaroos had no tails, they would topple over" (Lewis, 1973b). "If an hour ago I had taken two aspirins instead of just a glass of water, my headache would now be gone" (Rubin, 1978). Perhaps the most obnoxious counterfactuals in any language are those of the form: "If I were you, I would …."

Lewis (1973a) observed the connection between counterfactual conditionals and references to causation. He finds these logical constructions in the language used by Hume in his famous discussion of causation. Hume defined causation twice over. He wrote, "we may define a cause to be *an object followed by another, and where all the objects, similar to the first, are followed by objects similar to the second*. Or, in other words, *where, if the first object had not been, the second never had existed*" (Lewis, 1973a: italics are Lewis's).

Lewis draws attention to the comparison between the factual first definition where one object *is* followed by another and the counterfactual second definition where, counterfactually, it is supposed that if the first object 'had not been' the second object would not have been either.

It is the connection between counterfactuals and causation that makes them relevant to social science research. From the point of view of some authors, it is difficult, if not impossible, to make any sense of causal statements without using counterfactual language (Lewis, 1973a; Holland, 1986; Rubin, 1978; Robins, 1985, 1986). Other authors are concerned that using such language gives an emphasis to unobservable entities that is inappropriate in the analysis of empirical data (Dawid, 1997; Shafer, 1996). The discussion here accepts counterfactuals in discussions of causation and will explain their role in the estimation of causal effects based on the work of Neyman (1923, 1935), Rubin (1974, 1978), and others.

We begin with a simple observation. Suppose that we find that a student's test performance changes from a score of X to a score of Y after some educational intervention. We might then be tempted to attribute the pretest–posttest change, $Y - X$ to the intervening educational experience, that is, to use the gain score as a measure of the improvement due to the intervention. However, this is social science and not the tightly controlled 'before–after' measurements made in a physics laboratory. There are many other possible explanations of the gain, $Y - X$. Some of the more obvious are simple maturation, other educational experiences occurring during the relevant time period, and differences in either the tests or the testing conditions at pre- and posttests. Cook and Campbell (1979) provide a classic list of 'threats to internal validity' that address many of the types of alternative explanations for apparent causal effects of interventions. For this reason, it is important to think about the real meaning of the attribution of cause. In this regard, Lewis's discussion of Hume serves us well. From it we see that what is important is what the value of Y *would have been* had the student *not had* the educational experiences that the intervention entailed. Call this score value, Y^*. Thus enter counterfactuals. Y^* is not directly observed for the student, that is, they *did have* the educational intervention of interest, so asking for what their posttest score *would have been* had they *not had it* is asking for information collected under conditions that are contrary to fact. Hence, it is not the difference $Y - X$ that is of interest, but the difference $Y - Y^*$, and the gain score has causal significance relative to the effect of the educational experience only if X can serve as a substitute for the counterfactual Y^*. In physical science laboratory experiments such a substitution is often easy to make, but it is rarely believable in many social science applications of any consequence.

A formal model or language for discussing the problem of estimating causal effects (of the form $Y - Y^*$ rather than $Y - X$) was developed by Neyman (for randomized experiments) and Rubin (for a wide variety of causal studies) and will be called the Neyman–Rubin model for causal effects here.

Prospective Causal Studies

The Neyman–Rubin model is most easily understood in the context of a *prospective causal study* that has the general structure specified by this sequence of events:

1. Subjects or experimental units of study are identified.
2. Baseline or pretest information about these units is recorded.

3. The units are either assigned to (in a controlled study) or select themselves to (in studies without the control of assignment) exposure to one of the treatment conditions or interventions of the study.
4. These units are then subsequently exposed to their assigned or self-selected treatment condition (and each unit is affected by this exposure in a manner that is unrelated to the exposure conditions of the other units).
5. At an appropriate later time an outcome, end point, or posttest measure is recorded for each unit in the study.

The type of study that this five-part schema is intended to cover includes most randomized comparative experiments as well as many types of pretest–posttest quasi-experiments or observational studies. It should be emphasized that, properly interpreted, the Neyman–Rubin model has application to other types of causal studies (see Holland, 1988; Holland and Rubin, 1988; Robins, 1997), but, for our purposes here, prospective causal studies are already sufficiently complicated and inclusive.

The condition mentioned parenthetically in (4), that the exposure conditions of the other units do not affect the outcomes associated with a given unit, is very important, and is clearly an assumption that would not be true in general (Hong and Raudenbush, 2013). For example, in the study of infectious diseases your vaccination will affect my likelihood of contracting polio. Rubin explicitly identifies this assumption calling it the stable unit treatment value assumption, or SUTVA. SUTVA will be assumed throughout this article.

The Neyman–Rubin Model

The version of the Neyman–Rubin model used here is adapted from that of Holland (1986), and differs from the original versions by Neyman (1935) and Rubin (1978) mainly in its emphasis on population quantities. One of the main benefits of this model is that it identifies certain 'counterfactual conditional expectations' as the location of key assumptions about the inferential structure of any causal study and its resulting data.

The prospective causal study begins with the 'units,' 'subjects,' or 'cases' of the study, and the ith unit is denoted by the subscript 'i.' It may help the reader to imagine that this is a discussion about a very large sample of units. Denote the population of units under study by P. For the most part P will lie quietly in the background without being noticed. The baseline information that is collected or recorded for unit i will be denoted as a *vector* of numerical information, z_i.

There is a 'causal' variable denoting a set of possible 'treatments' or 'exposure' conditions to which each unit in the study could be exposed. For simplicity, we assume that there are only two treatment conditions denoted by $x = 1$ (treatment) and $x = 0$ (control). A more complicated version of this would let x be a number representing the 'strength' of the treatment level, but we will just use the dichotomous case here.

An important aspect of causal variables designating such treatments levels or intervention conditions is the assumption that the level of exposure for any unit *could have been different* from what it actually was. This condition excludes 'attributes' of units (such as race, gender, age, or pretest score) as causal variables in the sense that such attributes *cannot* have 'unit-level causal effects' in the sense that we will define below. This idea is discussed more extensively in Holland (1986, 1988), and is mentioned again in another context at the end of the present article. Each unit is exposed to one treatment level and the value of x to which i is exposed is denoted by x_i.

Finally, we come to the outcomes or dependent variables in the study, and here is where a special notation is needed. We let $Y_i(x)$ denote the (numerical) response that would be recorded for unit i if unit i were exposed to treatment level x. For each i, $Y_i(x)$ is a function of x. It should be emphasized that $Y_i(x)$ is not directly observed unless $x_i = x$. This is an important point because it is crucial to realize that the $\{Y_i(x)\}$ do not denote *observed data* like z_i and x_i do, but rather the $\{Y_i(x)\}$ are 'potential outcomes' that lie behind the observed values of the outcome variable (Rubin, 2005). For this reason, we denote the potential observations by capital letters to distinguish them from quantities that are directly observable, which we denote by lowercase letters.

The connection between the potential outcomes and the actually observed outcomes is then given by the equation

$$y_i = Y_i(x_i) \qquad [1]$$

where y_i is the observed outcome or value of the dependent variable for unit i. The idea behind eqn [1] is that to get from the potential outcomes $\{Y_i(x)\}$ to an observed outcome, we must select the value of x in $Y_i(x)$ to be the value to which i is actually exposed, that is, $x = x_i$, and then we obtain y_i from the potential observations, $\{Y_i(x)\}$, via eqn [1].

The *observed data* for each unit i are the vector (z_i, x_i, y_i). The potential outcomes, $\{Y_i(x)\}$, are never observed for *all* values of x for a fixed unit, i, but only for the specific x-value to which i is actually exposed, x_i. It is sometimes said that the $\{Y_i(x)\}$ are 'counterfactual' because they are not actual observations. Here they are called *potential observations* because they could have been observed had x_i been different than it was.

It is helpful to use a notation, such as $E(y)$, to mean the average value of y_i across the (large number of) units in P. Furthermore, an expression such as

$$E(y|x = a) \qquad [2]$$

will mean the average value of y_i across all of the (large number of) units in P for which $x_i = a$. The use of the expectation notation is to make certain quantities clearer in their meaning, and may be justified from either a frequentist or Bayesian point of view. It should be noted that within the expectation notation, the subscript i, denoting the unit, is suppressed because, within the scope of the $E(\ )$ operator, i is averaged over.

Using the Neyman–Rubin Model

An important fact about the Neyman–Rubin model is the Fundamental Problem of Causal Inference (Holland, 1986): It is impossible in principle to *observe* $Y_i(x)$ for more than one value of x for any one unit, i. Any procedure that claims to have avoided the Fundamental Problem of Causal Inference can always be shown to be based on untestable assumptions.

Sometimes such assumptions are plausible, and sometimes they are not.

A basic definition that we are now in a position to make is that of a 'unit-level causal effect.' Because we are restricting attention to the simple case of two treatment levels, $x = 0/1$ we may restrict attention to these differences

$$Y_i(1) - Y_i(0) = \text{the casual effect of } x = 1 \text{ relative to } x = 0 \text{ for unit } i \quad [3]$$

In the Neyman–Rubin notation, the unit-level causal effects are the *basic* quantities of interest in causal inference. However, the Fundamental Problem of Causal Inference is now immediately seen to *be fundamental* because it implies that unit-level causal effects are, themselves, *never directly observable*. Thus, we are always reduced to making assumptions that allow us to make some sort of conclusion or inference about these causal effects. This is the place where the Neyman–Rubin model might appear to be impractical for applied research, that is, because its most basic parameters, the unit-level causal effects, are not directly observable. Furthermore, this is exactly the place where the potential exposability of all of the levels of x to any unit is seen to be crucial to the foundations of the theory. The definition of causal effect requires this assumption so that the difference, $Y_i(1) - Y_i(0)$, is meaningful. It is the Fundamental Problem of Causal Inference and this definition of causal effect that make causal inference both more interesting and more difficult than the simple computation of correlational and associational measures. The unit-level causal effects mimic the comparison between a 'factual' and a 'counterfactual' identified in the quote mentioned earlier from Hume by Lewis.

It is now time to introduce the notion of an average causal effect (ACE). In general, an ACE is any average of unit-level causal effects. The most general ACE has the form

$$\text{ACE} = E[Y(1) - Y(0)|A] \quad [4]$$

where A denotes some collection of units defined in terms of either z_i or x_i or both. In eqn [4] we again suppress the subscript i because it is being averaged over. As an example of an A in eqn [4] we might use $A =$ 'all the units in the study,' in which case the ACE is the average causal effect over all of P. But other cases might be of interest, for example, $A =$ 'all units where i is male and for whom $x_i = 1$.' In this case the ACE is for the males in treatment group 1. Here we restrict our attention to the ACE that is called the 'effect of the treatment on the treated' in which case A denotes all of the units for which $x_i = 1$, that is

$$\begin{aligned}\text{ACE} &= E[Y(1) - Y(0)|x = 1] \\ &= E[Y(1)|x = 1] - E[Y(0)|x = 1]\end{aligned} \quad [5]$$

Up to now, we have simply defined the basic structure of the data collection design as well as the causal connection between the potential outcomes and the causal variable x, that is, eqn [3]. We have not yet identified the connection between any quantities that could be estimated with data and the causal parameters given by either the unit-level causal effects in eqn [3] or the ACEs in eqn [5]. This leads us to the 'prima facie average causal effects,' (FACEs). The FACEs are what can be estimated from the data. To parallel the ACE in eqn [5] we examine the FACE, which is simply the difference between the mean of the outcome variable observed in each treatment group, that is

$$\text{FACE} = E[y|x = 1] - E[y|x = 0] \quad [6]$$

If we substitute the definition of y in terms of the potential observations, $\{Y_i(x)\}$, that is given in eqn [1] into eqn [6] we obtain

$$\text{FACE} = E[Y(1)|x = 1] - E[Y(0)|x = 0] \quad [7]$$

Finally, if we combine eqn [5] and eqn [7] we obtain the following basic formula that relates the ACE to the FACE

$$\text{FACE} = \text{ACE} + \text{BIAS} \quad [8]$$

where

$$\text{BIAS} = E[Y(0)|x = 1] - E[Y(0)|x = 0] \quad [9]$$

The BIAS term contains two parts: one *factual*, that is, $E[Y(0)|x = 0] = E[y|x = 0]$, and the other *counterfactual*, that is, $E[Y(0)|x = 1]$. The factual part is just the mean of y_i for those units with $x_i = 0$. The counterfactual part is the mean of $Y_i(0)$ for those units for whom $x_i = 1$. $E[Y(0)|x = 1]$ is a quantity for which there can never be any data because the conditioning event makes the quantity being averaged over a counterfactual. Thus, it is a counterfactual conditional expectation. The value of such counterfactual parameters is that they pinpoint exactly where assumptions must be made that allows causal inference to take place using empirical data. When BIAS = 0, we have FACE = ACE and the empirical FACE equals the causal ACE.

An important condition that insures that BIAS = 0 is the construction of x_i by random assignment, which forces x_i and $Y_i(0)$ to be statistically independent of each other as functions of i over P (Holland, 1986). When this independence holds, $E[Y(0)|x = 1] = E[Y(0)|x = 0]$ and BIAS = 0.

Empty Counterfactuals

There is an unsatisfactory and rather misleading use of counterfactuals that sometimes arises in social science research. It occurs when the counterfactual condition, that is, the 'if A were the case' part could never occur in any real sense. Such empty counterfactuals arise when a nonmanipulable factor in a causal study is described as having an 'effect' on some outcome. Examples easily come about in casual causal talk. The effect of gender on salary suggests considering "what her salary would have been had she been a man." The effect of test performance on future employment suggests "the job he would have had had he scored higher on the test." The effect of English language proficiency on a math test in English suggests "the mathematics score a non-English speaker would have received had he or she been an English speaker." These empty counterfactuals arise when the value of a variable for a factor in a study could not have been other than the value that it was. The interesting and useful counterfactuals arise in those cases when the variable could have had a different value than it did for the individuals in a study, at least in principle. Judgment as to when a counterfactual is empty or not is not always easy and may require careful thought in many cases (King and Zeng,

2006). Consider the examples "if I were you, I would …," Lewis's kangaroo, and Rubin's aspirin in the opening paragraph. These represent very different kinds of counterfactuals from this perspective. The first is as empty as they get, the emptiness of the second depends on how the kangaroo might not have a tail (our imagination vs an axe), while Rubin's aspirin could be taken or not.

Abstract

This article discusses causal inference in statistics. It describes the theoretical framework and notation needed to formally define causal effects and the assumptions required to identify them nonparametrically. This involves definition of potential outcomes that represent the potential value of the outcome across different treatment exposures. Designs that allow researchers to satisfy or weaken these assumptions are briefly described. Then common parametric assumptions used to model effects and more current approaches that require weaker assumptions are discussed.

Introduction: Causal Inference as a Comparison of Potential Outcomes

Causal inference refers to an intellectual discipline that considers the assumptions, study designs, and estimation strategies that allow researchers to draw causal conclusions based on data. As detailed below, the term 'causal conclusion' used here refers to a conclusion regarding the effect of a causal variable (often referred to as the 'treatment' under a broad conception of the word) on some outcome(s) of interest. The dominant perspective on causal inference in statistics has philosophical underpinnings that rely on consideration of counterfactual states. In particular, it considers the outcomes that could manifest given exposure to each of a set of treatment conditions. Causal effects are defined as comparisons between these 'potential outcomes.' For instance, the causal effect of a drug on systolic blood pressure 1 month after the drug regime has begun (vs no exposure to the drug) would be defined as a comparison of systolic blood pressure that would be measured at this time given exposure to the drug with the systolic blood pressure that would be measured at the same point in time in the absence of exposure to the drug. The challenge for causal inference is that we are not generally able to observe both of these states: at the point in time when we are measuring the outcomes, each individual either has had drug exposure or has not.

Notation for Potential Outcomes and Causal Effects

There is a long history of philosophers, statisticians, and economists thinking about causality and how to establish causal relationships between variables. This philosophical discussion continues to this day, with many different perspectives still being expressed (see, e.g., Pearl, 2009; Dowd, 2011). Statisticians have generally focused on the investigation of the extent to which a given 'cause' leads to a change in some outcome(s) of interest. This is the framework detailed in this article. More general discussions of causal relationships, such as those investigated through structural equation models or path analysis, or those that attempt to determine a (or the) cause of an effect, typically require much stronger assumptions than do approaches that focus on estimating specific causal effects (Holland, 1986; VanderWeele, 2012).

To formalize assumptions and models in this framework, traditional statistical notation has been extended to explicitly define the 'potential outcomes' described above (Rubin, 1978). For instance, for an individual, i, and a binary treatment, Z_i, two outcomes can be defined that have the potential to be observed at a given time point, $Y_i(Z_i = 0) = Y_i(0)$ and $Y_i(Z_i = 1) = Y_i(1)$. In common language, these can be described as the outcome that would be observed if individual i had not received the treatment ($Z_i = 0$) and the outcome that would be observed if individual i had received the treatment ($Z_i = 1$), respectively. In the context of the example of the effect of a drug on blood pressure, $Y_i(0)$ would reflect the systolic blood pressure at a particular point in time for individual i observed in the absence of the drug and $Y_i(1)$ would reflect the systolic blood pressure observed *at that same point in time* for individual i after treatment with the drug.

One benefit of the potential outcome notation is that it allows for a simple and clear definition of the individual-level causal effect for observation i as a comparison between these two potential outcomes, for instance, $Y_i(1) - Y_i(0)$. (Nonlinear comparisons of potential outcomes, such as those used to define an odds ratio can also be considered; for simplicity this article focuses on the simple difference, in part because of complications that arise with noncollapsible functions of the potential outcomes; see, e.g., Greenland et al., 1999; Austin, 2007.) This formalization makes explicit the difficulty in inferring causality at the individual level given that we can never observe both $Y_i(1)$ and $Y_i(0)$ for the same individual, at any given time point; Holland (1986) refers to this as the 'fundamental problem of causal inference.' Using this potential outcomes framework to define causal effects also allows us to define those effects nonparametrically, and creates a useful distinction between structural assumptions and modeling assumptions (discussed below).

While it is nearly impossible to empirically identify individual-level causal effects without very strong assumptions or very specialized settings (for instance, in a laboratory where conditions can be precisely controlled), it is possible to make progress with respect to estimating average causal effects. The most common such estimand is the average of individual-level causal effects over a population or sample of interest, expressed generally as $E[Y(1) - Y(0)] = (1/N)\Sigma_i(Y_i(1) - Y_i(0))$. When this average is taken over the full population of interest, it is

referred to as the population average treatment effect. When this average is taken over the analysis sample it is referred to as the sample average treatments effect (SATE).

There is also sometimes interest in causal effects for particular subgroups. As a simple example, researchers may be interested in the SATE for males as distinct from the SATE for females. A slightly more complex example is sometimes referred to as the 'average treatment effect on the treated' (ATT). This is the average treatment effect for those in the treatment group, and is defined as $E[Y(1) - Y(0)|Z = 1] = (1/N_t)\Sigma_\iota(Y_i(1) - Y_i(0)|Z_i = 1)$. (An analogous quantity called the sample average treatment effect on the control (SATC) can also be defined.) Researchers are sometimes interested in the ATT in settings where there is no thought of giving the treatment to the full population, and rather interest is in the effect of the treatment on the people who actually received it. This might be the relevant quantity, for instance, in studies of the effects of adolescent drug use, where there is no thought of 'imposing' drug use on all adolescents. The sample average treatment effect on the treated (SATT) in such a study would compare the average outcomes for drug users with the potential outcomes for the same group had they not used drugs. This could inform the potential effect of programs that help to prevent or terminate drug use in teenagers. The SATE, on the other hand, would represent the difference between the average potential outcomes if all adolescents in the study were heavy drug users versus the potential outcomes that would manifest if none of the adolescents in the study were heavy drug users. This would not be the relevant scientific quantity given that some portion of that sample would likely never choose to use drugs so the effect for these people is rather meaningless. See Imai et al. (2008) and Harder et al. (2010) for more discussion of possible estimands.

To illustrate some of these concepts, consider the hypothetical data in Table 1. These data reflect 14 participants in a study that aimed to estimate the effect of a job training program on hourly wages. The table presents an omniscient view of the data that the researcher could never see in entirety because the Y(0) cells for those in the treatment group and the Y(1) cells for those in the control group are complete. The column for Y denotes the outcome that is observed for each person: $Y = \text{Treat}*Y(1) + (1 - \text{Treat})*Y(0)$. Seeing this complete data set with all of the potential outcomes observed is of course not possible in the real world, but, for illustration, it allows us to see the causal effects for each individual and, by extension, to calculate several different sample estimands. The treatment effects vary in this example depending on whether the participant had received a high school education (HS). The subgroups without high school education (HS = 0) are all defined to have treatment effects of 4. On the other hand, those with a high school education would experience no gain from the job training (for each, $Y(0) = Y(1)$). Since the distribution of those with high school education varies across the treatment groups, the average treatment effects vary as well. The SATT is equal to 2.67 and the SATC is equal to 1.

Table 1 Displays data from a hypothetical job training study. Data on high school graduation status (HS), age, and hourly wage (Y) could be observed by the researcher. The full set of potential outcomes could not be observed. They are displayed here to aid in conceptualization of individual-level causal effects as well as several sample average estimands

Person	*Treat (Z)*	*HS*	*Age*	*Y(0)*	*Y(1)*	*Y*

Structural Assumptions Required for Nonparametric Identification

If we could observe all of the potential outcomes for our sample, then causal inference would be easy. However, as discussed above, the fundamental problem of causal inference reflects the fact that at best we can observe only half of the potential outcomes, and thus need to rely on assumptions about those missing potential outcomes. In some sense this is what distinguishes causal inference from standard statistical inference, in that it (generally) requires untestable assumptions regarding the unobserved potential outcomes. This section discusses the structural assumptions needed to estimate causal effects, followed by a brief discussion of possible study designs and additional parametric assumptions.

Ignorability

Unconditional Ignorability

What assumption would allow us to identify average causal effects? To make the issues concrete, consider each piece of the SATE. Estimating $E[Y(1)]$ for the sample is challenging because we only observe Y(1) for those observations that were assigned to receive $Z = 1$. If those observations assigned to $Z = 0$ have a different mean of Y(1) than those who were assigned to $Z = 1$, then an estimate of the mean of the treated outcomes, $E[Y(1)|Z = 1]$, will be a biased estimate of $E[Y(1)]$. Similarly, estimating $E[Y(0)]$ is challenging because we only observe Y(0) for those observations that were assigned to receive $Z = 0$. If those observations assigned to $Z = 1$ have a different mean of Y(0) than those who were assigned to $Z = 0$, then an estimate of the mean of the control outcomes, $E[Y(0)|Z = 0]$, will be a biased estimate of $E[Y(0)]$. The most straightforward set of assumptions that ensures that a simple difference in means can provide an unbiased estimate of the average treatment effect relies on mean independence:

$$E[Y(0)] = E[Y(0)|Z = 0]$$

$$E[Y(1)] = E[Y(1)|Z = 1]$$

Designs and estimation procedures discussed in a later section highlight the distinction between assumptions and estimation. However, it is worth mentioning at this point that a completely randomized experiment would automatically satisfy this mean independence assumption. In fact, it will satisfy an even stronger assumption, that the distributions of the potential outcomes are independent of the binary outcome Z: $Y(0), Y(1) \perp Z$. Because of the connection to this classic design in causal inference, this assumption, sometimes referred to as the ignorability assumption, is also referred to as the randomization assumption.

The other estimands discussed above require slightly weaker assumptions. For instance, the effect of the treatment on the treated can be decomposed into two pieces, $E[Y(1)|Z = 1]$ and $E[Y(0)|Z = 1]$. Since we observe $Y(1)$ for the treated ($E[Y(1)|Z = 1] = E[Y|Z = 1]$), it is straightforward to estimate $E[Y(1)|Z = 1]$. However, it is difficult to estimate $E[Y(0)|Z = 1]$, since we do not observe $Y(0)$ for any treated individuals. It only becomes straightforward if $E[Y(0)|Z = 1] = E[Y(0)|Z = 0]$. This would be a consequence of randomization of the treatment Z as well since that design ensures that $Y(0) \perp Z$. Similarly, $Y(1) \perp Z$ would allow us to estimate the effect of the treatment on the controls. While these are weaker assumptions than are necessary for identification of the average treatment effect, it is difficult to find situations in which one assumption is clearly more plausible than the other.

Ignorability

Unless a randomized experiment has been performed, the above version of the ignorability assumption is typically not plausible because it implies that there are no systematic differences between the treatment and control groups with respect to the potential outcomes. Therefore, many causal inference methods rely on the more general version of the assumption above that conditions on observed covariates, X, formalized as $Y(0), Y(1) \perp Z|X$. In words, this assumption requires that the treatment and control group members that have the same values of X are not systematically different with regard to their potential outcomes. Some authors refer to this formulation as 'conditional ignorability,' however, this nomenclature is redundant since the standard formulation of the assumption allows for conditioning on covariates.

A simple example in which we would know that the ignorability assumption holds would be a randomized block experiment in which the blocks are defined by covariates, X. Observational studies differ in a crucial way from randomized block experiments, however, because no explicit randomization occurs; thus, we must take it on faith that the ignorability assumption holds.

How does ignorability help? When the ignorability assumption holds it implies the following properties:

$$E[E[Y|Z = 0, X]] = E[E[Y(0)|Z = 1, X]] = E[E[Y(0)|X]] = E[Y(0)]$$

and

$$E[E[Y|Z = 1, X]] = E[E[Y(1)|Z = 1, X]] = E[E[Y(1)|X]] = E[Y(1)]$$

This means that if ignorability holds (conditional on X) and we can appropriately condition on X, then all we have to do is average these conditional means over the distribution of X and we can recover the marginal means of the potential outcomes. If X is not low-dimensional, however, this conditioning can prove difficult in practice, which has led to use of some of parametric, semiparametric, and sophisticated nonparametric approaches discussed below or in other articles.

Common Support

Satisfying ignorability ensures comparability (with regard to potential outcomes) across treatment and control groups for observations with the same values of the covariates. However, this is only helpful if there is *common support* across treatment groups with respect to the confounders. That is, there must be observations from both treatment groups for each neighborhood of the covariate space where we want to make inferences. If, for example, no control units exist for a given neighborhood of the covariate space where treated units exist, then, in essence, no 'empirical counterfactuals' exist for those treatment units and we cannot make causal inferences about them without further assumptions. For this reason, causal researchers often require an assumption of overlap or 'common support' when attempting to identify causal effects, typically formalized as $0 < \Pr(Z|X) < 1$. In a randomized experiment, this is operationalized by the fact that all individuals in the experiment have a positive probability of receiving either treatment condition; individuals who could not receive one of the treatments would be deemed ineligible for the study.

In practice, if researchers determine that this assumption is not satisfied, they might decide to perform inference only for observations in portions of the covariate space where both treated and control units exist. This may lead to a different causal estimand than originally intended and results must be interpreted accordingly (see, e.g., Crump et al., 2006). This trade-off in what is being estimated and how well it can be estimated is often of particular relevance in studies that use propensity score methods, discussed further in other articles on observational studies.

The determination of common support depends on the inferential goal. For instance, if the goal is to estimate the effect of the treatment on the treated, this would require that control observations exist in every neighborhood of the covariate space where treatment observations exist, but not vice versa. If there are parts of the covariate space where there are controls but no treated subjects, it does not matter for nonparametric identification of the ATT since the goal is not to make inferences about the controls anyway. This lack of overlap could influence parametric estimation, however.

Common support is the only standard causal inference assumption that is empirically verifiable. However, the usefulness of this property is hampered by two issues. The first is that researchers may condition on a large number of covariates in an attempt to satisfy ignorability and it becomes increasingly difficult to verify overlap as the dimensionality of the covariate space grows. A common approach to this problem is simply to examine overlap with regard to the propensity score (*see* Observational Studies: Overview). However, this requires correct specification of the propensity score model. The second issue is that even if the included covariates satisfy ignorability, they may represent a superset of the covariates

actually needed to satisfy ignorability. Researchers forcing common support with respect to all included covariates may make overly conservative judgments about which observations need to be discarded from an analysis. Alternatives exist that aim to satisfy *common causal support*, $0 < \Pr(Z|W) < 1$, which requires overlap only with respect to the subset of covariates needed to satisfy ignorability, W (Hill and Yu-Sung, 2013).

Stable Unit Treatment Value Assumption

The potential outcome notation introduced above has an assumption embedded in it. The potential outcomes for individual i under treatment and control conditions, respectively, were defined as a function of the treatment exposure for individual i alone, $Y_i(Z_i = 1) = Y_i(1)$ and $Y_i(Z_i = 0) = Y_i(0)$. This ignores the possibility that this outcome could be influenced by the treatments received by others. A more general formulation, $Y_i(Z)$, could define potential outcomes based on the full vector of treatments received by everyone in the study, Z. Even with a modest sample size, such a formulation would increase the complexity of the research questions and subsequent analysis beyond a reasonable limit, not to mention the impossibility of ever achieving common support. For instance, in a study with a binary treatment and 10 people this formulation would lead to $2^{10} = 1024$ different potential outcomes for each person. The assumption that each person's potential outcomes are only defined based on his or her own treatment assignment can be formalized by the following expression: $Y_i(Z) = Y_i(Z')$, if and only if $Z_i = Z'_i$. This assumption is often discussed colloquially as the 'no interference assumption' to reflect the requirement that one individual's potential outcomes cannot be changed by another person's treatment. However, implicit in the stable unit treatment value assumption (SUTVA) is also the assumption that the treatment and control conditions mean the same thing for all units. In other words, there is only one 'version' of the treatment condition and one 'version' of the control condition (see Hernan and VanderWeele, 2011 for more thorough discussion of this assumption and its implications).

The most common strategy for avoiding concerns about SUTVA violations is through study designs that assign treatments at the group level. For example, many studies of educational interventions randomize whole schools to treatment conditions rather than randomizing individuals within schools, due to concerns that the treatment received by one individual may affect the outcomes of other individuals in the same school. This interference is less of a concern when considering schools as the units.

Temporality

Implicit in our understanding of causality is the notion that our causal variable (or treatment) occurs temporally prior to the outcome. Moreover, when conditioning on covariates it is crucial that they represent events that occur or characteristics measured prior to the causal (treatment) variable, otherwise they are implicitly outcomes and need to be conceived as such. Rosenbaum (1984) presents a discussion of this issue as do other authors (such as Gelman and Hill, 2007). Conditioning on variables that may be affected by the treatment (e.g., mediators) brings in additional complexities because they require consideration of the potential values of those post-treatment variables. A framework for thinking about post-treatment variables, called principal stratification, is discussed further in the article with that name. Other approaches to exploring causal pathways posttreatment are discussed in the article on Mediation.

Design Considerations

Causal researchers have carefully considered the types of research designs that facilitate satisfying the required assumptions. Generally, randomized experiments are seen as the strongest design for estimating causal effects since ignorability is assured through the randomization. Randomization also obviates the need to fit models that condition on pretreatment covariates and makes inferences from such models (when used, for instance, to increase efficiency) more robust to departures from the parametric assumptions. However, randomized experiments are not always possible, and can have their own complications that make inferences challenging, such as noncompliance and missing data (Barnard et al., 2003). A final concern with randomized experiments is that they often enroll subjects that are not representative of the population of interest, potentially making them less useful for estimating population treatment effects (Imai et al., 2008).

A number of strong nonexperimental study designs exist for settings when randomized experiments are infeasible or do not answer the question of interest. A common theme across nonexperimental studies is the need to design them with as much (or more) care as is used for randomized experiments (Rosenbaum, 1999; Rubin, 2008). Some nonexperimental designs are motivated by the desire to avoid or make more plausible the assumption of ignorability of the treatment assignment. These designs include regression discontinuity, interrupted time series, fixed effects, and instrumental variables approaches. They are discussed in more detail in other articles on Observational Studies.

Other nonexperimental study designs are motivated by the desire to avoid or weaken parametric assumptions by creating as much balance and overlap across treatment and control groups as possible. Matching and stratification (with or without propensity scores) are the most prominent designs in this genre. This type of 'preprocessing' (see Ho et al., 2007) can allow either for nonparametric inference on the newly constructed treatment and control groups (for instance, by comparing mean outcomes across matched treatment and control groups) or for more robust inference using standard parametric models (for instance, by fitting a regression on matched treatment and control groups). Treatment effect estimation is more robust to deviations from the parametric models when the treatment and control groups have common support and are well balanced (that is, the covariate distributions are similar across groups).

Nonexperimental studies of all types are ideally designed in ways that limit their sensitivity to unobserved confounding (violations of ignorability). Rosenbaum (2004) formalizes this

in a concept called 'design sensitivity' and Zubizarreta et al. (2013) provide one example of implementing these ideas in practice, such as comparing extreme values of a continuous treatment variable, matching on a large set of observed characteristics, and tying the statistical test used to the hypothesized pattern of effects. Gelman and Hill (2007) and Shadish et al. (2002) provide more information on nonexperimental study designs, and cite relevant articles on observational studies.

Parametric Assumptions

The focus of this article thus far has been on identification of causal effects through nonparametric approaches (comparisons of means or subgroup-specific means). It can be difficult to maintain a completely nonparametric approach in situations where it is necessary or beneficial to condition on covariates. For instance, if ignorability requires conditioning on covariates, then we must find a way to model the requisite conditional expectations. A straightforward approach to such conditioning is by fitting a linear regression model to the observed data. In particular, if one assumes that $Y(0) = X\beta + \varepsilon_0$ and $Y(1) = X\beta + \tau + \varepsilon_1$, then regressing observed Y on X and Z would be a reasonable approach for estimating τ. However, we rarely believe that such simple additive and linear models hold in practice, and it can be difficult to diagnose deviations from these models when X is high-dimensional or when there is lack of common support across treatment and control groups.

As discussed above, some designs (notably matching and stratification) are motivated by the desire to avoid these types of stringent parametric assumptions. However, an alternative (or complementary) approach is to simply use a semiparametric or nonparametric strategy when estimating causal effects. Examples of semiparametric estimation including regression models that incorporate weights based on the propensity score could also be considered to be a part of this paradigm (Hahn, 1998; Rosenbaum 1987; Hernan et al., 2001; Kurth et al., 2006). A more liberal interpretation might also frame weighting strategies as observational 'designs' because the goal is to create a 'pseudo-population' within which treatment and control groups are balanced. Nonparametric regression methods that can accommodate large numbers of covariates are typically Bayesian or computationally driven, or both (examples can be found in Hill, 2011 and Karabatsos and Walker, 2012).

Some causal inference approaches target the structural assumptions without considering the parametric assumptions. For instance, classic fixed effects models are often used in causal inference settings as a way of capturing group-level confounders that are not directly measured (*see* Hierarchical Models: Random and Fixed Effects). However, these models are traditionally embedded in a classical linear regression framework with all the parametric assumptions inherent in that framework. Moreover there is no guarantee that such strategies will reduce rather than amplify bias.

Conclusions

This article has discussed the potential outcomes framework for defining and estimating causal effects, in particular determining the effects of treatments on outcomes. It has highlighted the key structural and parametric assumptions commonly made, and the implications of those assumptions in experimental and nonexperimental settings. For more information on the details of estimating causal effects please see the other associated articles in this volume.

Causation: Physical, Mental, and Social

Abstract

Many philosophers hold (what might be called) the causal hierarchy picture of the world. The picture is hierarchical because it views social entities (institutions, groups, or corporations) as being composed of psychological entities (persons or individuals), which are themselves composed of biological entities (cells), which are themselves composed of fundamental physical entities (atoms and subatomic particles). The picture is causal because it assumes that causal statements are potentially true at every level in the hierarchy. While attractive, the picture raises an important question about how any upper level causal statements can be true. On the one hand, it seems part of the picture that upper level causal statements are true only if corresponding lower level statements are, but on the other, if the corresponding lower level statements are true, there seems no reason for supposing that the upper level statements are true in the first place. This article discusses the formulation of the problem in contemporary philosophy and its relation to a different but superficially similar problem that was historically raised against Cartesian dualism. The article also suggests that the problem emerges in the causal hierarchy picture only from a mistaken interpretation of a common causal principle, usually called the exclusion principle.

We invoke the notion of causation to describe many different aspects of our experience and of the world. For example, in describing the physical domain, we might say the earthquake caused the building to collapse; in describing the psychological or mental domain, we might say paranoia was the cause of Oswald shooting Kennedy; and in describing the social domain, we might say excessive military spending caused instability in the Soviet Union. In addition, we often use causal notions to link these various domains together. For example, we might say her arm rose because she wanted to signal, linking the mental domain (wanting to signal) and physical domain (her arm rising); or social policy causes the degradation of the environment, linking the social domain (social policy) and the physical domain (the environment). In short, causation is a very general notion: it applies in and across the physical, mental, and social domains, and perhaps others too. According to many philosophers, however, there is an interesting and difficult class of problems that emerges when we focus on how causal statements in one domain – for example, the physical domain – interact with causal statements in others – for example, the social or mental domains. Problems in this class – which we will call problems of causation in multiple domains – is what this article is about (for causation in general, *see* Causes and Laws: Philosophical Aspects).

Cartesian Dualism and Gassendi's Objection

The seventeenth century philosopher and mathematician Rene Descartes famously held that, while the nature and behavior of nonhuman animals could be explained completely by the physical science of his day, various features of human beings – including in particular the fact that human thought and action are not under direct environmental control – seemed to place them beyond the reach of physical science. Descartes therefore endorsed dualism, the idea that every human being is a complex of a physical body located in space and subject to physical laws and an immaterial mind not located in space and not subject to physical laws. Descartes' contemporary Gassendi famously objected that dualism made a mystery of how bodily actions and movements could be caused by immaterial psychological events: 'How can there be effort directed against anything, or motion set up in it, unless there is mutual contact between what moves and is moved? And how can there be contact without a body?' (Descartes et al., 1984).

Gassendi's objection is an example of a problem of causation in multiple domains. It turns on the fact that there is causal contact between the mental and physical domains, something that is difficult to understand if Cartesian dualism is true. However, problems of this sort are by no means unique to the relationship between the mental and the physical, nor to Descartes' specific account of that relationship, and nor do they arise only from older ideas in science and philosophy. On the contrary, they arise from a general picture of the world, which is very common in contemporary intellectual culture: the causal hierarchy picture.

The Causal Hierarchy Picture

What sort of picture of the world does contemporary science presents us with? According to one common view, science presents us with a twofold picture. One part of the picture is that the world is organized into a series of levels (cf. Oppenheim and Putnam, 1958; Schaffer, 2003). The most basic level (assuming there is a most basic level) is the physical level, which is described by the most basic science, physics. Arranged in a hierarchy on top of this level are other levels such as the chemical level, the biological level, the psychological level, and the social level, and each of these levels are described by nonbasic sciences (sometimes called special sciences), such as chemistry, biology, psychology, and sociology. To put things the other way around, the picture views social entities (institutions, groups, or corporations) as being composed of psychological entities (persons or individuals), which are themselves composed of biological entities (cells), which are themselves composed of chemical entities (molecules), and which are themselves composed of fundamental physical entities (atoms and subatomic particles).

Another part of the picture adds causation to the hierarchy, in two distinct ways. First, it is part of the picture that, since

causation is a very general notion, causal statements are true at every level. Thus, causal claims about the behavior of corporations or persons are, from the point of view of the picture, perfectly genuine and potentially true. Second, it is also part of the picture that every time a causal statement is true at some nonbasic level, there is a corresponding causal statement that is true at the basic level.

The intuitive idea behind this second point is that causal statements at higher levels require mechanisms at lower levels, and, ultimately, at the physical level. Thus, consider the statement, she raised her arm because she wanted to signal. According to the picture, this statement (if true) is made true by, and requires for its truth, a further statement drawn from a lower level, presumably a statement about neural activity and how that activity causes movement of the limbs. Or again, consider the statement, urbanization in Australia in the twentieth century resulted in a decline of religious practice. This statement (if true) is made true by, and requires for its truth, a further statement drawn from a lower level, presumably a statement about the thoughts and goals of particular people that made up the relevant populations. In both cases, causal statements at upper levels require mechanisms at lower levels.

Many aspects of this causal hierarchy picture have been discussed and examined in recent philosophy of (natural and social) science (*see* Social Properties (Facts and Entities): Philosophical Aspects). But for our purposes, the important point is that it raises a problem of causation in multiple domains, and in fact a whole class of such problems. Here is a simple way of seeing the issue. Consider some causal statement *S*, which is putatively true at some nonbasic level *N*. Given the causal hierarchy picture, there will be another causal statement *S**, which is true at the basic level *B*. However, if *S** is true, and we know it is true given our picture of science, why should we suppose in addition that *S* is true? Intuitively, after all, all the causal work – all the pushing and shoving – is done at the basic level. But then it is mysterious why *S* – or any nonbasic causal claim – should be true.

While the issues are sometimes assimilated, the problem generated by the causal hierarchy picture is different from the problem that Gassendi raised for Descartes, in two respects. First, Gassendi's objection flows from the fact that, for Descartes, the physical and the mental domains are so different in nature: one is in space, the other not. But the problem raised by the causal hierarchy picture does not have its source in the fact that the mental level is so different in nature from the physical level. Its source is rather the simple fact that upper level causal claims are distinct from (i.e., not identical with) lower level claims, together with the idea that every time a causal claim is true at some nonbasic level, a corresponding causal claim will be true at the basic level. Second, the problem generated by the causal hierarchy picture is not limited to the mental and physical domains, as was Gassendi's objection. As we have seen, it arises for any nonbasic causal claim, whether in biology, psychology, or social theory. So long as one supposes that there are causal claims at these levels, a problem of causation of multiple domains can be raised.

We can now see the significance of the problem of causation in multiple domains. On the one hand, we have a picture of the world, the causal hierarchy picture, which is presented to us by science and therefore has a reasonable claim to be our best and most sophisticated picture of the world. On the other hand, the problem of causation in multiple domains apparently tells us that picture cannot be right, because the picture itself makes it hard to see how any nonbasic causal statements can be true.

The Exclusion Argument

We have so far been concerned with presenting the problem generated by the causal hierarchy picture in an informal way. However, it is desirable to be a bit more explicit about the reasoning that leads to the problem. The crucial fact about this reasoning is that it exploits a principle about causation often called the exclusion principle (Kim, 1993, 1998; Yablo, 1992; Bennett, 2003). As we shall shortly see, the precise formulation of this principle is a matter of controversy, but a reasonable initial formulation is (E1):

(E1) If e_1 causes e_2, then there is no event e_3 such that: (a) e_3 is not identical to e_1 and (b) e_3 causes e_2.

Intuitively, the idea here is that the discovery of a cause for some phenomenon usually means that other causes have been ruled out or excluded. For example, if a doctor tells you that the pain in your foot is caused by uric acid crystals in the joint of your big toe, you do not regard it as an open question whether the pain has some other cause – calcium crystals, for example.

With the exclusion principle in place, we can now be more explicit about the problem generated by the causal hierarchy picture. It is easiest to state the argument if we focus on a particular kind of causal statement, one in which a certain nonbasic event n causes a physical event p. (Later we will consider whether this assumption is misleading.) Thus, suppose that (1) is true

(1) n causes p.

Given the causal hierarchy picture, it would seem that there must be a physical event p*, which also causes p; hence (2) is true:

(2) p^* causes p.

Now, given that n and p* are from different domains, i.e., are drawn from different levels, we may further assume that

(3) n is distinct from (i.e., not identical to) p^*.

However, the principle of exclusion – in the form of (E1) – says that, in general, no two distinct events can cause a single event. Hence,

(4) abc

(4) If n is distinct from p^*, then it is not the case that both n and p^* causes p.

But (1)–(4) are jointly contradictory: while any three of them might be true, all four cannot be true together. It follows (barring some subtle ambiguity) that at least one of (1)–(4) must be false. In other words, what the reasoning tells us is that the causal hierarchy picture together with the exclusion principle presents a contradiction. To solve the problem, one must

give up or modify either the exclusion principle or the causal hierarchy picture or both.

Possible Responses

The most common response to the exclusion argument is to modify the principle of exclusion. Before turning to that response, however, it is important to briefly consider some alternative possibilities.

Rejecting the Hierarchy Part of the Picture

One obvious response is to suggest that the causal hierarchy picture is a distorted picture of the world because it takes the metaphor of levels too literally. This objection might go as follows. While it is true that there are apparently lots of different sciences, this is only a methodological or pragmatic fact, which represents our limited epistemological access to the world. In fact, there is only a single science – physics – which genuinely explains the world. The other sciences are simply convenient descriptions, which, apart from their pragmatic usefulness, will or could be dispensed within the future.

The main problem with this position is a feature of the causal hierarchy picture that so far has not been discussed: multiple realizability. Earlier we saw that according to the causal hierarchy picture, entities from upper levels are composed of entities from lower levels. But it seems an obvious empirical fact that the same entities from an upper level might be composed of many different entities at lower levels. Thus, the same corporation over time might be composed of different individuals. The same mental processes in different people might be made up of different neural processes – indeed, given science fiction possibilities, they might not even be made of neural processes at all. The lesson usually drawn from multiple realizability (as these sort of facts are called) is that entities from upper levels are genuinely distinct from lower level entities and, as a corollary, that the sciences dealing with upper level entities are genuinely distinct from lower level sciences (Fodor, 1974/1981); see Kim (1993) for an opposite view. However, if this is the right lesson, one should take seriously the hierarchy part of the causal hierarchy picture.

It is important to note that drawing this lesson from multiple realizability does not represent a return to Cartesian dualism. One can see this if one introduces another feature of the causal hierarchy picture: supervenience. Philosophers often say that, in the causal hierarchy picture, the upper levels supervene on the basic level, where this means that, while the upper levels in the hierarchy are distinct from the basic level, they are nevertheless wholly determined by, or are entailed by, the basic level (cf. Kim, 1993). A simple way to think of supervenience is by switching metaphors from levels to patterns. To say that the psychological or the social supervene on the physical is to say that these are patterns in the physical – hence are wholly physical – it is simply that they are not patterns that physicists are interested in. To put the point a little more formally, supervenience tells us that if you imagine a possible world that completely matches the actual world in all physical respects, then you have *ipso facto* imagined a possible world that also matches the actual world in all psychological and social respects. But this idea is something that Descartes would have denied. According to Descartes, the psychological (and presumably the social also) is only contingently related to the physical, and thus a possible world that completely matches the actual world in physical respects is not necessarily a world that completely matches it in these other respects.

Rejecting the Causal Part of the Picture

If one cannot reject the hierarchy part of the causal hierarchy picture, can one reject the causal part? One way to develop this objection starts with the observation that it is not at all obvious that particular sciences make explicit use of causal notions. Bertrand Russell (1917/1963) famously claimed that physics had no use for causation. More recently, many have argued convincingly that causation has no place, or at least no central place, in the explanations offered by particular special sciences such as psychology, linguistics (Chomsky, 1959; Cummins, 1983), and anthropology (Sperber, 1996). So perhaps the proper account of the picture of the world that science presents is that it is hierarchical but not causal.

However, while it might very well be true that particular sciences do not provide explicitly causal explanations, this does not mean that various causal claims will not be true at the various levels. We can see this if we examine briefly the dispute between Chomsky and Skinner, surely one of the central moments of twentieth-century science (Chomsky, 1959). Skinner had proposed, among other things, that the basic aim of scientific psychology and linguistics should be to provide causal explanations of human behavior – functional analysis, Skinner called it. Part of Chomsky's response to Skinner was that it is premature to suppose that scientific psychology could provide such explanations. He suggested instead that a more reasonable aim for scientific psychology would be the decomposition of certain psychological capacities and abilities, and in particular the ability on the part of a speaker to speak a language. I think it is fair to say that, in this regard, Chomsky's suggestion has been enormously influential and that most cognitive psychologists follow him in not aiming at causal explanations of behavior. However, even if this is true, it also remains true both that there are truths about how behavior is caused, and that these truths are in all probability multiply realized. But then we have the problem of causation of multiple domains back again.

One can imagine a more radical development of this point, where the claim at issue is not that causation plays no role in the explanations offered by special sciences, but rather that no nonbasic causal claims are true. In fact, this idea has been historically popular in philosophy of mind and psychology. In part because of the influence of Wittgenstein, it was at one time very common to hear that causal talk in the psychological domain either should not be taken seriously or should be interpreted very differently from similar talk deployed in the physical domain (Ryle, 1949; for criticism, see Davidson, 1963/1981). But suggestions of this sort consistently underestimate the sense in which causation is an extremely abstract and general notion. W.V.O. Quine famously argued that the difference between the statements 'cows exist' and 'numbers exist' is not a difference in existence, but rather a difference between cows and numbers. Similarly, one might

say that the difference between causal claims in the physical domain and, e.g., the psychological domain is not a difference in causation; it is simply a difference between physics and psychology.

Rejecting the Metaphysical Presuppositions of the Picture

Finally, a number of philosophers have attempted to avoid the exclusion argument by suggesting that it only arises from mistaken metaphysical views lying behind the causal hierarchy picture. For example, in stating the exclusion argument above, we assumed that an upper level event might cause a lower level event – (1) summarizes just that possibility. According to some philosophers, however, this sort of 'downward causation' is deeply mysterious, and causation takes place only within levels, not across levels (cf. Kim, 1993). However, if one rejects downward causation, one might reject the exclusion argument right from the start.

However, the problem with this suggestion is twofold. First, it is not clear that downward causation is so mysterious. As we have noted a number of times, causation is an extremely general notion. There seems no reason in principle why we should not suppose that upper level events might not cause lower level ones. Second, it seems possible to formulate the exclusion argument even if one does not start by assuming that downward causation is possible. For consider: given the causal hierarchy picture, every nonbasic event will supervene on some basic event. But then, one could causally explain the presence of any nonbasic event by causally explaining the basic event on which it supervenes. This brings the problem back again: given the causal hierarchy picture, there seems no rationale for supposing that any nonbasic causal statement is true.

Problems with Exclusion

If we cannot answer the exclusion argument by rejecting the causal hierarchy picture or some metaphysical presupposition of the argument, it would seem that the only option left is to give up or modify the exclusion principle. Indeed, objections to this principle are easy enough to find. Consider the spy shot by the firing squad: the first soldier on the firing squad caused his death, but so did the second. Hence, the spy's death is overdetermined. But a little reflection shows that the exclusion principle as stated so far rules out cases of overdetermination a priori.

This objection to the exclusion principle is suggestive but limited. It is true that there are possible cases of overdetermination. But it still seems unlikely that every case of nonbasic causation should be analogous to the case of the firing squad. To accommodate the possibility of overdetermination, we can reformulate the exclusion principle to read

E(2) If e_1 causes e_2, then (probably, in general) there is no event e_3 such that: (a) e_3 not identical to e_1 and (b) e_3 causes e_2

(E2) allows, where (E1) does not, the possibility of firing squad cases, but it also says that we can expect such cases to be the exception rather than the rule. On the other hand, it seems clear that we could formulate a probabilistic version of the exclusion argument based on (E2), which would be almost as bad as the nonprobabilistic version based on (E1).

A second objection to the exclusion principle cuts deeper, however. Consider the possibility of composition (or multiple realizability) all the way down: whenever we arrive at a potential basic level, it turns out that this level is itself composed at a lower level (for discussion of this idea, see Schaffer, 2003). Combining this idea with the exclusion principle yields some absurd results. For if there is composition all the way down, it is easy to see that the exclusion argument will tell us that any candidate causal statement is false. But this suggests that there really is something wrong with the exclusion principle. Surely a principle of causation should not have the consequence that no candidate causal claim is true.

In response to this objection, a proponent of the exclusion principle might take one of two options. First, one might deny the possibility that there is composition all the way down. However, this is a fairly desperate maneuver. It is surely an empirical question, not a question that can be decided a priori, whether the levels of the world simply go on forever. Second, and much more plausibly, one might revise the exclusion principle to accommodate the objection. The obvious way to do this is to replace 'identical to' in (E2) with 'supervenient on,' invoking the relation we discussed in the context of multiple realizability. That would result in the following principle:

E(3) If e_1 causes e_2, then (probably, in general) there is no event e_3 such that: (a) e_3 not supervenient to e_1 and (b) e_3 causes e_2

This version of the exclusion principle does not have the result that, if the world is composed all the way down, none of our paradigm causal claims are true. For it is consistent with (E3) that causal claims can be true at levels that supervene on the basic level. Thus, even if we assume that there is composition at every level, it is still consistent with (E3) that some causal claims at nonbasic levels are true.

On the other hand, if it is (E3), and not (E1) or (E2), which provides the proper articulation of the exclusion principle, then we have a response to the exclusion argument. The exclusion argument mistakes (E1) for (E3). Combining the causal hierarchy picture and (E1) yields a contradiction, but there is no problem with combining the causal hierarchy picture and (E3), for (E3) does not exclude the possibility of nonbasic causal claims.

Further Questions

Problems of causation of multiple domains threaten to undermine our picture of the world. But, as we have seen, these problems arise only from a mistaken conception of the exclusion principle, i.e., only if we formulate that principle as (E1) or (E2) and not (E3). However, it would be a mistake to conclude that this is the end of the matter. For (E3) generates some further puzzling questions of its own. I will close by briefly mentioning two of these.

The first question arises when we consider the difference between (5) and (6):

(5) For some events e_1, e_2, and e_3, if e_1 causes e_2, and if e_3 supervenes on e_1 then e_3 causes e_2

(6) For all events e_1, e_2, and e_3, if e_1 causes e_2, and if e_3 supervenes on e_1 then e_3 causes e_2

(E3) allows the possibility that (5) is true. But it had better not allow the possibility that (6) is. For (6) is subject to counterexamples such as the following (Jackson and Pettit, 1990). Suppose living in a particular neighborhood on the north side of town (e_1) makes you happy (e_2); living in a particular neighborhood on the north side of town entails living on the north side of town – as we might put it, living on the north side of town (e_3) supervenes on living on a particular neighborhood on the north side (e_1). Nevertheless, it might not be true that living on the north side (e_3) makes you happy (e_2) – after all, with the exception of your own particular neighborhood, you may dislike the north side, thinking of yourself as a 'south side person.' But now we are faced with a problem: if (6) is not true and (5) is, how are we to draw the line?

In order to answer this problem, Jackson and Pettit appeal to a principle of causation they call invariance of effect under variance of realization. They go on to develop this principle, embedding it in a framework for thinking about the relation between causation, causal explanation, and the causal hierarchy picture (especially as that applies to the social and psychological realms), which they call program explanation (cf. Jackson and Pettit, 1990, 1992; Pettit, 1993; for some similar work, see List and Menzies, 2009). Unfortunately, reviewing these ideas is beyond the scope of the present discussion. But the important point is that the idea that (E3) articulates the exclusion principle incurs an obligation: to explain what distinguishes the event triples $\langle e_1, e_2, e_3 \rangle$ that satisfy (5) from the event triples that do not.

The second question returns us to Gassendi's objection to Descartes. In response to Gassendi's objection, many Cartesian dualists are tempted to endorse epiphenomenalism. Epiphenomenalists accept that there is a correlation between mental events and behavioral events, but insist that the correlation in question is not causal. Rather, the correlation is the product of two other relations: a nomological (or lawful) relation between brain events and psychological events, and a causal relation between brain events and behavioral events. Since these latter relations can obtain without a causal relation obtaining between mental events and behavioral events, epiphenomenalism is a possible position, no matter how counterintuitive it seems to suppose that mental events do not cause behavioral events.

The problem that epiphenomenalism presents for (E3) and our discussion of it is the following. If we restrict attention to the relation between the psychological level and the neurological level, we too have articulated a correlation between mental and behavioral events, and for us too the correlation is a product of two further relations: first, there is a supervenience relation between the mental event and the brain event; second, there is a causal relation between the brain event and the behavioral event. However, why should we suppose that this correlation is causal? As the case of epiphenomenalism makes clear, the mere fact that a correlation is a product of a causal relation and some other relation does not make the correlation causal. Perhaps then, the answer we have given to the exclusion argument is no better than the epiphenomenalist answer to Gassendi?

Part of the answer to this question is that there are correlations and there are correlations. True, the fact that a correlation is the product of a causal relation and some other relation does not make it causal. But it had better not make it noncausal either – after all, every causal relation is a product of a causal relation and identity. So the structural similarity between the account we have offered and epiphenomenalism does not entail that account is no better than epiphenomenalism.

But there is also a somewhat deeper issue here. The world presents us with a myriad of correlations. Our concept of causation is in part a tool to divide these correlations into the causal and the noncausal. Obviously, there are some correlations that are clearly causal and some that are not. But it needs to be admitted that there are hard cases, cases in which it is difficult to say whether we have a causal correlation here or not. The causal hierarchy picture that we have been discussing presents us with such hard cases. Adopting a concept of causation that employs (E1), these cases will turn out not to be causal; adopting a concept of causation that employs (E3), they will. As we have seen, the latter concept does seem a reasonable concept of causation. But defending that choice in detail requires more investigation of the concept of causation that we can enter into here.

Causes and Laws: Philosophical Aspects

Abstract

The questions 'what makes it the case that one event causes another?' and 'what makes it the case that something is a law of nature?' are highly controversial ones for which, among contemporary philosophers, there is no answer that can claim orthodoxy. This article sketches some of the most influential theories of causation and lawhood.

Preliminaries

'Cause' and 'law' are perhaps two of the most important and fundamental concepts that human beings deploy in their attempts to understand and intervene in their environment, both in everyday life and in their scientific endeavors. When we want to explain why an event occurred, we seek out its causes. When we act, we do so because we believe the action will have certain effects. When we want to know why our environment and our fellow human beings behave in regular, predictable ways, we look for the laws that govern that behavior.

It is part of the scientist's job to discover what causes what, and to investigate what the laws of nature are. The philosopher's job, however, is a more abstract one; the philosopher wants to know what makes it the case that something – anything, be it the decay of a subatomic particle or the assassination of Archduke Ferdinand – causes something else, or that something is a law of nature – whether it is a physical, biological, psychological, economic, or any other kind of law. We know that when one strikes a match and it lights, the first event – the striking – caused the second. But this causal fact depends for its truth on more than the mere fact that the two events occurred one after the other; there must be some extra feature of the world that binds these two events together as cause to effect. Similarly, it seems that laws of nature must be more than mere regularities; it is doubtless true that all lumps of gold are smaller than a mile in diameter, but it is not a law that this is so. So genuine laws must have some extra feature, apart from regularity, which marks them off from mere 'accidental' regularities. The philosopher's job, or at least part of it, is to say what, if anything, this 'extra feature' might be.

Determinism vs Indeterminism

A question that is relevant to any discussion of the nature of causes and laws is that of whether the universe is fundamentally deterministic or indeterministic. One way of putting the thesis of determinism is this: the complete state of the universe at any given time together with the laws of nature determines precisely what the complete state of the universe will be at all future times. Indeterminism is simply the denial of determinism.

The view that the universe is fundamentally indeterministic has been widely (although by no means universally) held within science since the advent of quantum mechanics; however, most philosophers only began to take the possibility of indeterminism seriously in the 1960s and 1970s. One consequence of this reluctance to take indeterminism on board is that some current theories of causes and laws were originally formulated under the assumption of determinism, and were then modified to take into account the possibility that at least some laws and causal processes are fundamentally indeterministic. The theories of laws and causation discussed below are mostly presented in their simpler, deterministic form. While the indeterministic versions of the theories present additional complications and problems – for example, because they employ the notion of probability – the fundamental philosophical issues addressed, and problems faced, by the indeterministic and deterministic versions, are mostly the same or similar.

The Particular and the General: Events, Facts, and Properties

Many of our causal claims are claims about individual occurrences: the assassination of Archduke Ferdinand, the Great Recession, the birth of a particular child, a specific meteor shower, or whatever. Such occurrences are thus the 'relata' of particular or 'token' causal relations. There is an ongoing debate about whether such individual occurrences should be conceived as events (the assassination of Archduke Ferdinand) or facts (the fact that Archduke Ferdinand was assassinated) – see, for example, Mellor, 1995 and Lewis, 1986 – but for simplicity we shall assume that they are events.

Sometimes, however, we make general causal claims about whole populations rather than their individual members. Thus, it is doubtless true that smoking causes cancer, but it does not follow that every individual who smokes will be caused to get cancer as a result; and it can be true that a particular person dies as the result of a bee sting without its being true that bee stings in general cause death. General or 'population-level' causation is generally taken to apply to properties or repeatable features that different individuals can share, such as smoking, getting cancer, being red, or weighing 3 kg.

Laws of nature are likewise concerned with general relationships between properties – whether it is the relationship between force, mass, and acceleration enshrined in $f = ma$ or the economic 'law' of diminishing marginal utility. In what follows, general features or properties will be denoted 'F,' 'G,' and so on, while individual events will be denoted 'c,' 'e,' etc.

Laws of Nature

Laws vs Accidents

What is the difference between laws of nature and merely 'accidental' regularities? (Suppose that it is a law that all metals expand when heated and that it is merely accidentally true that all (past, present, and future) Queens of England are less than 2 m tall.) A crucial difference is that laws 'support counterfactuals,' whereas accidental regularities do not. It is true of any unheated piece of metal that if it were to be heated it would expand. But it need not be true of any non-Queen of England that if she were to be Queen she would be less than 2 m tall. If someone is currently, say, 2.05 m tall, becoming Queen of England would not result in her getting any shorter.

Another difference is that violations of law are said to be physically impossible, whereas violations of accidental regularities are physically possible. It is physically impossible for a heated metal to fail to expand when heated; but it is perfectly possible for a Queen of England to be taller than 2 m. Finally, it is sometimes claimed as a third difference that laws, unlike accidental regularities, 'govern' what goes on in the universe. We tend to suppose that statements of laws of nature are rather like pieces of divine legislation: decrees that the universe must obey rather than mere general descriptions of what in fact happens.

Realist vs Regularity Accounts of Laws

Can an analysis of lawhood be given that does justice to these intuitions about the nature of laws? A popular view (Armstrong, 1983) is that laws are relations of necessitation between universals. To say that it is a law that all *F*s are *G*s is to say that there is a necessary relation, *N*, that holds between the universals (properties) *F* and *G*. (Following Armstrong, we can write this '*N*(*F*,*G*)'.) When an object instantiates *F*, the instantiation of *F* guarantees, via *N*, that *G* will also be instantiated. Thus, *N*(*F*,*G*) – its being a law that all *F*s are G*s* – guarantees that all *F*s will in fact be *G*s.

The basic point of this 'realist' theory of laws is that it provides an 'ontological ground' for the difference between laws and accidents; accidental regularities just happen, whereas lawful regularities are grounded in and explained by a necessary relation holding between the co-occurring properties. And, on this view, sense can be made of the idea that laws govern what happens; if *N*(*F*,*G*) holds, then *G* must be instantiated whenever *F* is instantiated.

The main rival to this conception of laws is the 'Humean' or 'regularity' conception, according to which laws are really no more than regularities. The classic (although not the only) motivation for the regularity view is an 'empiricist' epistemology according to which we ought not to believe in entities that we cannot perceive. Since our evidence that there are any laws of nature comes solely from the observation of regularities – when we see a law (as opposed to an accidental regularity) being instantiated we do not see any extra ontological feature – we ought not to believe that there is any extra ontological feature that laws have but accidental regularities lack.

A 'naïve' regularity theory, however – according to which statements of law are merely true universal generalizations – is untenable, for it simply collapses the distinction between laws and accidental regularities. If statements of law are merely true universal generalizations, then accidental regularities are themselves laws; it turns out to be a law of nature that no Queen of England is taller than 2 m after all.

A more sophisticated version of the regularity theory is provided by the 'Ramsey–Lewis view,' after F.P. Ramsey and David Lewis (see Lewis, 1973b: pp. 73–75; J.S. Mill also held a similar view). The basic idea of the Ramsey–Lewis view is as follows. When we seek, as scientists do, to find out how the universe behaves, we are not satisfied with isolated facts about what happened in the laboratory on Tuesday afternoon, what happened when a particular patient took a particular drug, and so on. Rather, what we seek are wide-ranging generalizations that abstract as far as possible from the particularities of the laboratory or the patient. Generalizations about the heights of Queens of England or the diameters of lumps of gold apply to an extremely restricted number and range of phenomena. On the other hand, generalizations about subatomic particles, chemical reactions, the relationship between force, mass, and acceleration, and so on, apply to an enormous number of diverse phenomena, and are hence much more useful and explanatorily powerful. According to the Ramsey–Lewis view, the difference between laws of nature and merely 'accidental' regularities amounts to roughly this difference between generalizations that are wide ranging and powerful and those that are not. It is not that there is any ontological distinction between laws and accidents – laws do not have an extra feature (*N*, say) that accidental regularities lack; rather, it just so happens that some generalizations (the laws) are interesting and useful ways of codifying what happens in the universe, and others (the accidents) are not.

The Ramsey–Lewis view (and the Humean view of lawhood in general) diverges from a conception of laws of nature according to which laws 'govern' what happens in the Universe, since on the Humean view the laws just are regularities, rather than features of the world that explain why the world is regular (Beebee, 2000). Some philosophers argue that Humeanism about laws makes it impossible for us to know any laws of nature (Armstrong, 1983: pp. 52–59; Bird, 2008; Beebee, 2011). On the other hand, some philosophers claim that Humeanism about laws takes the sting out of the alleged conflict between determinism and free will (see Swartz, 1985: Chapters 10 and 11; Beebee and Mele, 2002; Berofsky, 2012) (*see* Free Will and Action).

Ceteris Paribus Laws

The accounts of laws canvassed above are perhaps best suited to the laws we find in, say, physics and chemistry – the places where we are most likely to find truly exceptionless generalizations that hold across the whole of space and time (although it is often argued that even in the 'hard' sciences, truly exceptionless generalizations are extremely rare). There are plenty of generalizations in, say, economics, sociology, and psychology that, while not exceptionless, are clearly lawlike in some sense. The law of diminishing marginal utility, for example, does not hold in all cases, so if lawhood requires an exceptionless regularity, there will turn out to be no laws in economics.

On the other hand, it is surely no accident that, by and large, the utility of something eventually decreases as one obtains a greater quantity of it. Similarly, there are plenty of generalizations in biology and psychology that are not exceptionless but nonetheless provide a good foundation for prediction and control.

Such cases are generally thought of as '*ceteris paribus*' laws ('cp-laws' for short): generalizations that hold not in all cases *simpliciter*, but only 'other things being equal,' that is, in cases where there is no additional, interfering factor. We might try to subsume cp-laws under our existing accounts of laws simply by building in the absence of such interfering factors, so that our candidate law has the form 'all *F*s are *G*s, except in circumstances *X*, *Y*, and *Z*.' This approach is problematic, however, since in many, if not most, cases, we either have no idea what the relevant *X*, *Y*, and *Z* are, and so – even if there is a law in the offing – we will not be in a position to formulate it, or else there will be indefinitely many ways in which the generalization in question could in principle fail, so there is no way in principle of specifying what the relevant law is.

We might try to avoid these problems by claiming that cp-laws are only supposed to hold in 'ideal' or 'normal' conditions, thus removing the need to specify exactly what those conditions are within the content of the law itself. However, unless we can independently specify which conditions count as normal or ideal, the threat of circularity looms; we cannot allow 'normal' or 'ideal' conditions to simply be those in which the regularity obtains, or cp-laws will turn out to be trivially true (all *F*s are *G*s – except when they are not). (See Hausman, 1992: Chapter 8; Pietroski and Rey, 1995; Earman and Roberts, 1999; Schrenk, 2007a.)

Stability and Invariance

Some contemporary accounts of lawhood take a different starting point to the idea that a law is an exceptionless regularity of a certain kind (the Ramsey–Lewis view) or else is the obtaining of some metaphysical relation that entails the existence of an exceptionless regularity (Armstrong's view). Instead, they start from the idea that the distinctive feature of laws is that they are stable or invariant under a range of different background conditions. Suppose that the generalization 'all the pens currently on Obama's desk are blue' is true. Despite being true, it is highly unstable; there are very many possible situations in which it would be false. Obama might, for example, have left the red pen he was using earlier today on his desk rather than putting it in his pocket, or one of his aides might have left their own black pen on the desk. By contrast, 'nothing travels at the speed of light' is highly stable; there are (so we currently believe) no physically possible situations at all that would render it false. The notion of stability is thus a 'modal' notion; the stability or otherwise of a generalization is a matter of whether it would still be true in various different, nonactual situations. And, since stability is not all-or-nothing but rather comes in degrees – one generalization can be more or less stable than another – we can think of lawhood itself as coming in degrees, so that some generalizations are more lawlike than others, rather than thinking that a generalization either expresses a law or it does not.

The notion of stability (or invariance) may be a good place to start if we want to make sense of cp-laws, because it seems to capture what is 'lawlike' about, say, the law of diminishing marginal utility. While the generalization in question only holds *ceteris paribus*, it arguably still exhibits a good deal more stability than, say, the generalization concerning the pens on Obama's desk; it would remain true (*ceteris paribus*) given a wide range of changes in prices, consumer preferences, and so on. Of course, we still need to find a way to spell out the restrictions imposed by the *ceteris paribus* clause; it has been suggested that we think of cp-laws as generalizations that are stable across circumstances that are of particular interest to a given science, such as psychology or economics (see Lange, 2002; Woodward and Hitchcock, 2003a,b).

Laws and Dispositions

A final kind of account of the nature of laws – again, one that is perhaps well suited to dealing with cp-laws – is a 'dispositionalist' account. According to a naïve version of the so-called counterfactual account of dispositions (such as fragility, which, when applied to panes of glass and china cups at least, we can think of as the disposition to break when dropped), an object *o* (a china cup, say) has disposition to manifest feature *M* (being broken) in 'stimulus conditions' *S* (being dropped) just if, if *o* were to be in situation *S*, it would manifest *M*. As it stands, however, this account cannot be right. For example, if I were to drop a china cup that is wrapped in a lot of cotton wool, it would not break – but the cup is nonetheless fragile. The presence of the cotton wool 'masks' the disposition – it prevents the disposition from being manifested. Antidotes provide another counterexample to the naïve counterfactual account; the redback spider is deadly (its bite has the disposition to kill people) despite the fact that, thanks to the existence of an antivenom, nobody has died from a redback bite for many years.

Whether the counterfactual account can be amended to deal with problem cases such as these is a controversial question (see e.g., Lewis, 1997; Bird, 1998). What is relevant to the discussion of laws, however, is that we can think of laws of nature as describing not how things actually behave, but how they are disposed to behave. So a candidate law of nature might have the form 'all *F*s are *D*s,' where property *D* is the disposition or capacity to be *G*, rather than 'all *F*s are *G*s' (Cartwright, 1989; Ellis, 2002; Bird, 2005).

A dispositionalist account of laws may be well suited to deal with cp-laws because – as we have just seen – something's having a disposition is compatible with its failing to manifest that disposition even though the stimulus condition is present. If we think of laws as generalizations about dispositions, then we can think of cp-laws as those laws that describe dispositions that are susceptible to masks, antidotes, and the like. Thus, for example, 'all china cups break when dropped' is false; I can easily falsify it by dropping a china cup wrapped in cotton wool. But this does not falsify 'all china cups are disposed to break when dropped,' since, as we have seen, a china cup is still disposed to break when dropped – it is still fragile – even if, thanks to the cotton wool, it is not in a position to manifest that disposition when I drop it. (See Schrenk, 2007b.)

Causation

Theories of causation have proliferated in the last 50 years or so, with different theories speaking to different underlying metaphysical commitments and to different views about how the ontology of causation (i.e., how the world has to be arranged in order for causal claims to be true) ought to relate to its epistemology (i.e., how we can come to know, or justifiably believe, that a causal claim is true). This section surveys some of the leading theoretical approaches.

The Naïve Regularity Theory

The agenda for much of the contemporary discussion about the nature of causation was set by Hume (1748/1975: Sections IV–VII). Hume was an empiricist, believing that there could be no 'ideas' in the mind that do not somehow come from our senses. How, then, do we come to have an idea of causation? What features of the world could furnish us with that idea? Famously, Hume maintained that we do not perceive any intrinsic connection or relation between two events we judge to be causally related; we see the match being struck, and we see it light, but we do not see any causation between those two events. Causation, then, cannot be a mysterious intrinsic relation between events – for if it were, since we cannot perceive any such relation, we could have no idea of causation. (See Menzies, 1998; Beebee, 2009 for discussion of the question of the observability of causation.)

The exact nature of Hume's positive theory of causation is a matter for interpretative dispute (see Beebee, 2006a). However, the standard interpretation – and therefore the one that has had the most impact on contemporary discussion – characterizes Hume as a 'naïve regularity theorist.' On this view, two events are related causally in virtue of contiguity (causes and their immediate effects are right next to each other in space and time), temporal priority (causes precede their effects), and constant conjunction (events similar to the cause are always followed by events similar to the effect). So what makes it true that the striking caused the lighting is that the two events are contiguous (or, if there is some spatiotemporal gap between them, the events are mediated by further events so that there is a chain of contiguous events starting with the striking and ending with the lighting); the striking occurs before the lighting; and similar strikings are always followed by similar lightings. The constant conjunction requirement ensures that for Hume (and for most modern day Humeans) causation is an extrinsic relation: a causal relation obtains between two events not purely in virtue of how those events themselves are, but in virtue of features of other events; the striking only gets to count as a cause of the lighting because other strikings are also followed by lightings.

The other notable feature of the naïve regularity theory is that it is a reductionist view: causal claims, like 'the striking of the match caused the lighting,' are made true, at bottom, not by any primitive causal feature of the world, but by noncausal features (since the fact that two events are contiguous, the fact that one occurs before the other, and the fact that they are similar to other events are not themselves causal facts).

The naïve regularity theory is now universally regarded as untenable, although, as we shall see, elements of it are clearly discernable in many contemporary theories. It is untenable for a variety of reasons. For example, the contiguity requirement rules action at a distance (one event's causing another, spatially or temporally distant event without there being a chain of events 'hooking up' the first to the last) to be impossible, while many philosophers think that is at least conceptually possible. And the constant conjunction requirement is obviously flawed: there can be constant conjunction without causation – for example, joint effects of a common cause are constantly conjoined but neither causes the other – and, if determinism is false, it seems there can be causation without constant conjunction. My betting on number 13 on the roulette wheel is a cause of my winning some money, even if in exactly the same circumstances the following day I bet on number 13 and lose.

Nevertheless, the general issues that Hume raised are still among the main foci of dispute in contemporary philosophy of causation. In particular, the question of whether causal facts reduce, somehow or other, to facts about regularities is the driving force behind many of the theories of causation currently on offer.

Counterfactual Analyses

Arguably, the most influential analysis of causation in recent years has been Lewis's counterfactual analysis (Lewis, 1973a). According to Lewis's analysis, an event e causally depends on event c if e counterfactually depends on c – which is to say, if, had c not occurred, e would not have occurred either (*see* Counterfactual Reasoning, Quantitative: Philosophical Aspects and Counterfactual Reasoning, Qualitative: Philosophical Aspects). A 'chain of causal dependence' is a series of events $\langle a, b, c, \ldots, n\rangle$ such that b causally depends on a, c causally depends on b, and so on. Finally, c causes e if there is a chain of causal dependence (perhaps involving only c and e themselves, but perhaps involving many hundreds of intermediate events) from c to e.

The need for chains of dependence arises when there is no counterfactual dependence between cause and effect because of a backup mechanism or 'preempted alternative.' Suppose that the bus stop is next to the taxi rank. Susan takes the bus to work (c); but if the bus had been late she would have taken a taxi. She attends a 9.30 meeting (e). e does not counterfactually depend on c, since if Susan had missed the bus she would have taken a taxi and attended the meeting just the same. But there is some intermediate event d – Susan's getting off the bus at the stop outside her office, say – which counterfactually depends on c (if she had not got on the bus in the first place, she would not have got off it either) and upon which e counterfactually depends (if she had not got off at that stop – given that she was already on the bus, and it was already nearly 9.30 – she would have had to walk back to her office from the next stop, and she would have missed the meeting).

Lewis's counterfactual analysis of causation has been found to be subject to a number of counterexamples (e.g., Schaffer, 2000a). Much recent work on causation has been devoted to devising alternative analyses which, while remaining true to Lewis's basic claim that causation is to be analyzed in terms of counterfactuals, add further complexities in an attempt both to circumvent the problem cases and to deal with

indeterministic causation (see, e.g., Menzies, 1989; Noordhof, 1999; Lewis, 2000).

Both Lewis's original analysis and its more complex successors fall squarely within the Humean tradition, since the counterfactual analysis is a reductionist project: it seeks to show how causal facts are made true by noncausal features of the world. Indeed, since Lewis's account of counterfactuals make the truth conditions of counterfactuals depend primarily on the laws of nature, and the laws of nature themselves, on Lewis's view, are merely a subset of the regularities, one can think of counterfactual analyses of causation generally as more sophisticated descendants of the naïve regularity theory of causation.

Not everyone, however, is a Humean. Many philosophers deny Hume's central motivating claim that causation cannot be perceived (see Anscombe, 1971; Armstrong, 1997: Chapter 14; Menzies, 1998; Beebee, 2009). Some argue that the features of the world to which reductionist analyses seek to reduce causal facts are themselves really causal features; hence reductionist analyses are circular and therefore unsuccessful (see Carroll, 1994). Others argue that if a broadly Humean analysis of causation were true it would render the pervasive regularities that the universe exhibits a sort of cosmic fluke (see Strawson, 1989: Chapter 5; Beebee, 2006b). And many simply think that the persistent failure of reductionist accounts to deal with counterexamples, despite ingenious amendments, is good reason to think that the whole reductionist project is doomed to failure.

Process and Mechanistic Theories

We generally take it for granted that causal influence is propagated through mechanisms or processes of various kinds. When the impact of the white snooker ball causes the black ball to roll into the pocket, we can grant that the latter event counterfactually depends on the former, but may yet be inclined to say that this dependence is symptomatic rather than constitutive of the causal relation between the two. This is because there is an identifiable process linking the two, involving the transfer of energy-momentum from the white to the black ball and subsequent movement of the black ball toward the pocket. Some philosophers have attempted to analyze causation by focusing on the distinction between a genuine causal process and a mere 'pseudoprocess.' Salmon (1984), for example, takes the distinguishing feature of causal processes to be their ability to 'transmit a mark.' A mouse walking across the floor is a process that can transmit a mark; for example, if I paint a blue patch on the mouse's fur, the blue patch will 'transmit' from earlier to later stages of the process (since it will go wherever the mouse goes). By contrast, if I make a spot of light move across the floor by means of a torch, the movement of the light across the floor is a pseudoprocess; if I paint the first illuminated patch blue, that mark will not transmit to later stages of the 'process'; it will stay just where I put it.

Salmon's 'mark transmission' theory is problematic for various reasons (see Dowe, 2008: Section 6). Dowe's suggested replacement, the 'Conserved Quantity Theory' (2000), identifies the causal relation with the transfer of whatever physical quantities are conserved according to the conservation laws of physics, for example, energy-momentum. A problem with this account is that it only tells us what causation actually consists in. It seems that we can imagine possible situations where there is causation in the absence of any transfer of a conserved quantity (e.g., by the casting of spells). Other analyses of causation – such as the counterfactual analysis – tell us why both the movement of snooker balls does, and the effective casting of spells would, count as cases of causation, since they both involve counterfactual dependence. Dowe's account fails to do this.

One solution to the problem is to attempt to spell out the 'folk theory' of causation: those features that, according to our ordinary concept of causation, are essential for a relationship to be causal, and hence those features that will apply to snooker balls and spells alike. And we can then claim that the transfer of conserved quantities counts as causation precisely because, as things actually are, it is such transfer that satisfies our folk theory or definition of causation – while at other possible worlds, such as one in which magic spells are effective, other kinds of relation count as causal (see Dowe, 2000: Chapter 1; Menzies, 1996; Lewis, 2004).

Like process theories, 'mechanistic' accounts of causation also seek to identify causation with the process by which the cause produces the effect (Glennan, 1996; Machamer et al., 2000; see Williamson, 2011 for a survey). However, mechanistic accounts are more pluralist in spirit, and do not try to locate a single feature of the world (such as the transfer of a conserved quantity) that can be identified with the causal relation. Machamer et al. note that "terms like 'cause' and 'interact' are abstract terms that need to be specified with a type of activity and are often so specified in typical scientific discourse. Anscombe (1971) … noted that the word 'cause' itself is highly general and only becomes meaningful when filled out by other, more specific, causal verbs, for example, scrape, push, dry, eat, burn, knock over. An entity acts as a cause when it engages in a productive activity" (Machamer et al., 2000: p. 6; see also Cartwright, 2004).

Dowe's account is explicitly reductionist in spirit, in two senses. First, it attempts to identify causation with a feature of the world that can itself be understood in noncausal terms; the 'transfer' of conserved quantities is not supposed to be conceived as, for example, the presence of an energy-momentum in the white ball causing its subsequence presence in the black ball. It is also reductionist in the sense that all (actual) causation is, at bottom, causation at the level of fundamental physics; the presence of a causal process is determined by features of the world that are visible, as it were, only from the perspective of physics. Machamer, Darden, and Craver's account is antireductionist in both senses. 'Productive' activities are not themselves to be analyzed in noncausal terms (e.g., the instantiation of regularities or the transfer of conserved quantities); nor are the mechanisms that underpin causal relations to be found only at the level of fundamental physics. Indeed, part of the purpose of their view is to make sense of causal explanation in biology.

Probabilistic Theories

Frequently, it is claimed on cigarette packets that smoking causes heart disease; this is a claim about 'general' or 'type-level'

or 'population-level' causation. What makes (or would make) such a claim true? We might try to regard it as some kind of generalization over individual instances of particular smokers whose heart disease has been caused by their smoking. But it is clearly not a universal generalization; the fact that Jane – a lifelong smoker – had no heart disease when she died from other causes (falling off a cliff, say) does not serve to refute the claim that smoking causes heart disease. Nor is our general causal claim merely an existential claim to the effect that at least one smoker has been caused by their smoking to develop heart disease. If that were so, then it would take just one unlucky person to die because of choking on a Mars Bar to make it true that eating Mars Bars causes imminent death.

This being so, we should perhaps regard general and 'token' or 'individual' causation as two different relations, the former relating types or properties, and the latter relating individual events or instantiations of properties – something that is suggested in any case by the grammatical form of general causal claims ('smoking causes heart disease,' and not 'instances of smoking cause instances of heart disease'). Indeed, some authors have argued that we have not only two different relations, but two relations that are independent of one another (e.g., Eells, 1991: Chapter 1). Others argue that the two 'levels' of causation are in fact closely related (Hitchcock, 1995), so that, once we have the right account of causation on the table, we will see that we do not really have two distinct species of causation at all.

What is generally accepted, however, is that general causation should be understood in terms of probabilistic or statistical relationships, so that, in essence, a claim of the form 'C causes E' is made true by C's raising the probability of E. (Similarly, 'C prevents E' is made true by C's lowering the probability of E.) According to one account (Eells, 1991; see also Suppes, 1970), we should understand C's raising the probability of E as the obtaining of $\Pr(E|C \,\&\, B_i) > \Pr(E|\sim C \,\&\, B_i)$, where B_1, B_2, … are all the different combinations of the presence and absence of other relevant factors within a given population. So, for example, suppose we divide our population (for example, UK citizens) into 'homogeneous reference classes,' so that within each reference class everyone is exactly alike with respect to all other risk factors for heart disease (alcohol consumption, cholesterol levels, relevant genetic factors, etc.). Then 'smoking causes heart disease' is true if and only if in each such reference class, Pr(heart disease|smoker) > Pr(heart disease|nonsmoker).

This condition is extremely hard to satisfy, however. For example, imagine that there is a very rare genetic trait that interacts with smoking in such a way as to decrease the risk of heart disease. Then on the above account it will be false that smoking causes heart disease for any population that includes possessors of this genetic trait as a subpopulation. A rival proposal (Dupré, 1984, 1990) is that C causes E if and only if C raises the probability of E in a fair sample of the population (i.e., in a sample of the population in which the relative frequency of other relevant factors is the same as it is for the population as a whole). This analysis yields the desired result that smoking causes heart disease in the above example, since in any fair sample those with the genetic trait will be vastly outnumbered by those who lack it; so C will still raise the probability of E in a fair sample. An alleged benefit of Dupré's analysis is that it makes the truth conditions for general causal claims match up in an obvious way with a standard way in which general causal claims are in fact established, namely, randomized control trials. The point of randomization is precisely to make it likely that other relevant factors are present with equal frequency in both the trial group and the control group, and an increase in frequency of the effect under investigation in the trial group relative to the control group is supposed to be good evidence that the drug, or whatever, is a cause of that effect.

The accounts just discussed are reductionist – indeed, Humean – in spirit, in that they seek to analyze (general) causation in terms of regularities (although the regularities in question are statistical rather than exceptionless). A more recent and similar approach – the 'manipulability' or 'interventionist' approach – shuns reductionism, but nonetheless aims to shed light on how causal structure can be inferred from statistical evidence (Woodward, 2003, 2008).

The need for the appeal to either homogenous reference classes or to fair samples stems in part from the need to rule out 'spurious causation;' cases of probability increase in the absence of causation. One factor F can easily increase the probability of another, G, in the population as a whole without causing G, as when, for example, F and G are effects of a common cause H. For example, the barometer needle pointing to 'rain' (F) is positively correlated with rain (G), but both are effects of a common cause, namely, low atmospheric pressure (H). (We can think of the population in this case as comprising 'weather episodes.') There will be no such spurious correlation in a homogeneous reference class, however, since by hypothesis all members of any such reference class will be alike with respect to whether or not they possess H. 'Holding fixed' factor H screens off the statistical relationship between F and G. Similarly, if we compare a fair sample of Fs with a fair sample of $\sim F$s, by definition H will have the same relative frequency within each of the samples, and so, again, there will be no correlation between F and G.

Interventionist accounts provide a different way of 'breaking' spurious probabilistic relationships. The basic idea is very simple. Take the barometer case again. F and G are positively correlated within the population as a whole. But if I intervene on F, say by manually moving the pointer so it either points to 'rain' (f_1) or to 'sunny' (f_2), the correlation disappears: there is no positive correlation between F and G if we consider just those cases where I have directly brought about either f_1 or f_2 (so long as my manually moving the pointer is not itself correlated with the atmospheric pressure). In effect, my intervening breaks the causal (and hence probabilistic) connection between the putative cause we are interested in – here, the position of the barometer needle – and its usual causes (atmospheric pressure).

A great advantage of the interventionist account is that, with the notion of an intervention in place, we can define causation in terms of increase in probability without the need to make any stipulations about other (relevant) background factors – unlike the probabilistic accounts considered previously. Interventionist accounts are not, however, reductionist accounts, since the notion of an intervention is itself defined in causal terms: an intervention is, by definition, the 'setting'

of a variable X (e.g., needle position) at a particular value x (e.g., 'rain') in a way that breaks the connection between (or 'screens X off' from) its usual causes.

One Concept of Causation or Two?

We can think of the various accounts of causation surveyed above as falling into two distinct categories. On the one hand, we have process and mechanistic accounts (Section Process and Mechanistic Theories), which take causation to be a matter of what we might call 'production'; on the other, we have counterfactual and probabilistic accounts, which take causation to be a matter of 'difference making.' Other analyses of causation not considered here are generally pretty easy to categorize as either 'production' or 'difference-making' accounts.

To see how these two notions can in principle come apart, consider a 'possible world' where much of what goes on is a result of spells cast by witches and wizards. Let us stipulate that the spells can operate at large spatial and temporal distances, and that they do so directly: there is no process or mechanism that connects the casting of a spell to its implementation. It seems right to say that when Merlin, at midday, casts a spell to turn the prince into a frog at midnight – which he duly does – the former caused the latter. Merlin's spell made a difference to what happened, but there was no process connecting the two; the former did not 'produce' the latter, in just this sense of 'produce' (Schaffer, 2000a). Or consider a less far-fetched scenario: Linda the lifeguard sees a swimmer in trouble and rushes to help, intent on preventing him from drowning. Tanya deliberately trips Linda up as she runs toward the sea, thus preventing her from preventing the swimmer from drowning. The swimmer duly drowns. (Such cases are known as cases of 'double prevention.') It seems plausible to say that Tanya's action is a cause of the swimmer's death; after all, had Tanya not tripped Linda up, the swimmer would have been saved. But again, there is no process connecting the two; we have the situation on the beach involving Linda and Tanya, and the swimmer way out at sea, with nothing linking them together. So again we seem to have difference making without production (Schaffer, 2000b).

It looks as though we can also have production without difference making. There are two routes of the same length to the shop – route A and route B. Which route I take makes no difference to the time and manner in which I arrive at the shop, but I am intent on going to the shop and will definitely take one or other of these routes; in fact, today I take route A. It looks as though my taking route A is not a difference maker: if I had not taken route A, I would have taken the route B, and I would have got to the shops just the same. However, there is clearly a causal process linking my setting out on route A and my subsequent arrival; I put one foot in front of the other, repeated a lot of times, and as a result reached the shop. So we have production without difference making.

Ned Hall (2004) argues that we really have two distinct concepts of causation: the production concepts and the difference-making concept. He diagnoses the repeated failure of various analyses of causation to cover the full range of standard problem cases by noting that analyses fall into either the production category or the difference-making category; so analyses of the former kind will inevitably fail to deal with cases of difference making without production, and analyses of the latter kind will inevitably fail to deal with cases of production without difference making. And, he claims, it is easy to fail to distinguish the two kinds of causation because cases of one without the other are pretty rare; in our ordinary dealings with the world, causes are both difference makers and producers of their effects. (When I sink the black ball in snooker, my taking the shot causes the black ball to drop into the pocket in both senses of 'cause.')

Many philosophers, however, have been reluctant to accept that there is no univocal concept of causation (Lewis, 2004). For example, Dowe (2001), whose Conserved Quantity Theory is clearly a 'production' account, argues that cases of difference making without production are not really cases of causation at all. Meanwhile, defenders of difference-making accounts argue that alleged cases of production without difference making can in fact be dealt with by their accounts. For example, we might respond to the shop case just described by appealing to the idea that causation is context-sensitive, in the sense that causal claims are true or false relative to contrast class (which is normally only implicit). Thus, my taking route A rather than route B really is not a cause of my subsequent arrival, since my taking route A rather than route B made no difference to the time and manner of my arrival. My taking route A to the shops rather than taking no route at all, however, is a cause of my arrival. So we can save the intuitive judgment that my taking route A is a cause of my arrival by finding a context within which the former does make a difference to the latter; hence we do not have a clear counterexample to a broadly difference-making account after all (Menzies, 2007).

Causes and Laws

The above discussion of causation and laws of nature has treated them as separate phenomena, to be given distinct analyses; yet intuitively there is some relationship between, for instance, the law that all metals expand when heated and the fact that a particular piece of metal's expansion is caused by its being heated. How, then, are causation and laws related?

Different theories of causation connect with laws of nature in different ways. Hume's constant conjunction requirement on causation, for example, can be seen as a requirement that causes and effects are lawfully correlated (or 'fall under' a covering law). Laws of nature enter into Lewis's counterfactual analysis of causation indirectly, via his analysis of counterfactuals (see Lewis, 1973b). For Lewis, the truth of 'if A had been the case, B would have been the case' requires that B is true at the 'closest possible world(s)' in which A is true, and closeness of possible worlds depends in part on the extent to which they share the same laws of nature. Dowe's Conserved Quantity Theory of causation (Section Process and Mechanistic Theories above) identifies the causal relation with the transfer of any quantity that is subject to conservation laws, so that, again, facts about causation depend on facts about the laws of nature – although in a rather different way. Heathcote and Armstrong (1991)

argue that the causal relation is identical with *N*, the relation of nomic necessity in virtue of which laws of nature obtain (see Section Realist vs Regularity Accounts of Laws above).

On the other hand, it has been argued that lawful correlation is not necessary for causation. Anscombe (1971), for example, holds that *c* may cause *e* even though *c* and *e* do not fall under any regularity. (Causation of this kind is sometimes referred to as 'singular causation'; but note that 'singular causation' can also be used to refer to particular causation, in contrast to general causation.) Heathcote and Armstrong (1991) claim that even though the causal relation is in fact identical with nomic necessity, this identity does not itself hold as a matter of necessity. Heathcote, Armstong, and Anscombe all agree, then, that 'higgledy-piggledy' worlds are conceivable – that is, possible worlds where there is plenty of causation but where causally related events are not subsumable under any laws (and so under any regularities) at all.

Abstract

Modern celebrity culture emerged as a focus of inquiry and critique in the mid-twentieth century, and has blossomed in recent years into a vibrant field of study. Critics have pointed to the role of celebrities as mass-produced commodities and celebrity as ideological support for consumer capitalism, and to the disconnection between notoriety and merit. Scholars have approached celebrities as symbolic entities, mediating a tension between egalitarian and aristocratic cultural tropes, and embodying cultural anxieties about the relationship between media images and lived realities; documented the economic, social, and political structures in which celebrity has been produced, noting the significance of the Hollywood star system, and the recent transformations brought by reality television and new media technologies; and studied celebrity fans and fandom, shedding light on forms of fan engagement with celebrity culture, fan–celebrity encounters, and the uses of celebrity images by marginalized groups.

In popular usage, 'celebrity' typically refers simply to the famous or notorious person, whose existence and activities are known to an audience that is unknown to him or her personally, or to the condition of such notoriety. Theory and research on the topic, while often focusing also on individual celebrities, have tended to work from a broader definition of 'celebrity' (or, occasionally, 'celebrityhood' or 'celebritydom'): as a social and cultural phenomenon, in which large-scale knownness and public visibility become important sources, measures, and currencies of social, economic, and sometimes political standing. Celebrities are generally defined as distinctly contemporary versions of famous people, and celebrity a distinctly contemporary form of fame. Their distinction is found in their relationship to modern, industrialized, commercial communications media, which makes it possible to achieve notoriety without benefit of extraordinary action or achievement. The celebrity is thus famous for the media-disseminated image of himself or herself; in Daniel Boorstin's (1961) well-known phrasing, he or she is "well known for his [or her] well knownness." Celebrities are, moreover, a specific kind of social elite or status group, characterized by both extraordinary privilege and uncertain boundaries, and whose members occupy positions that are both socially central and easily lost (Kurzman et al., 2007; see also Milner, 2005). They are, as Italian sociologist Francesco Alberoni (1972) put it, a 'powerless elite' – or more accurately, an elite with high status and visibility but limited institutional power – commanding a high level of interest unrelated to the consequences of their activity. The study of celebrity, which has emerged within both humanities and social science disciplines, has run along several overlapping tracks. Beginning with critics of mass culture, analysis has focused on the distinctive characteristics and symbolic functions of celebrity in contemporary Western societies; more structurally focused studies have considered the political, economic, and social organization of celebrity, especially as it has become industrialized in the entertainment business, spread across a variety of institutional settings, and undergone changes due to new media genres and technologies; and, more recently, researchers have investigated the interpretations, uses, pleasures, and sources of engagement for audiences or fans of celebrities and celebrity.

Celebrity and Critiques of Mass Culture

The term 'celebrity' in its modern meanings began to be used in the nineteenth century, but the study of the phenomenon began in earnest with the rise of mass-produced culture, and in particular with the elaboration of an industrialized Hollywood film 'star system' in the early decades of the twentieth century. (For an excellent history of fame and fame discourse from ancient times to the near-present, see Braudy, 1986.) It first emerged as a sustained focus of inquiry through mid-twentieth-century criticism of mass culture, from both the left and the right. Although these works were rarely based on empirical research, and were filled with unsupported assertions about those creating and receiving celebrity images, they called attention to the mass production and management of celebrities, and to the question of the social impact of industrialized celebrity culture.

The Celebrity and Capitalist Ideology

Early perspectives on celebrity were largely theoretical, emerging as part of Marxist-influenced Frankfurt School cultural criticism of 'mass culture,' 'mass society,' and the 'culture industry.' Celebrities were seen as mass-produced, standardized commodities posing as unique human individuals, and celebrity discourse as a major ideological support beam for consumer capitalism. In the 1940s, Theodor Adorno and Max Horkheimer (1977), for instance, saw celebrities as the products of 'the culture industry,' the cultural apparatus of mass society; Hollywood stars serve as distractions from the dissatisfactions created by industrial capitalism, and to manipulate 'the masses' into capitalism's false promises of both choice (standardized, mass-produced celebrities appear to be different individuals) and universal success (celebrities appear to demonstrate the rewards available to all).

Leo Lowenthal (1968), also writing in the 1940s, researched changes in 'mass idols' in popular magazines, charting the move from 'idols of production' (business and politics) to 'idols of consumption' (entertainment and sports); he too suggested that these popular culture heroes perpetuated the myth of an open social system, such that the existing social

system is celebrated along with the star. C. Wright Mills (1956: p. 71) wrote in the 1950s of the professional celebrity as a summary of American capitalist society's promotion of competition and winning; as "the crowning result of the star system in a society that makes a fetish of competition," the celebrity shows that rewards go to those who win, regardless of the content of the competition.

The definition of celebrities as mass-produced distractions, and their ideological role in promoting consumption, competition, individualism, and the myth of open opportunity, has continued in much contemporary cultural criticism and analysis. For example, P. David Marshall (1997: p. x), has argued that the celebrity, as a "public individual who participates openly as a marketable commodity," embodies and legitimates the linked ideologies of market capitalism and individualism; Chris Rojek (2001: p. 90) has located celebrities within 'the culture of distraction today,' as human commodities who fill the void left by 'the death of God and the decline of the church'; Ellis Cashmore (2006: p. 269) has concluded that "celebrity culture's most basic imperative is material: it encourages consumption at every level of society"; and Karen Sternheimer (2011: p. 24) has suggested that celebrity culture "reflects and reinforces the ever changing notion of what it means to achieve the American Dream."

Celebrity vs Heroism

For more conservative cultural critics from the 1950s onward, the role of the celebrity system as an ideological support for capitalism was less important than its reflection of a large-scale disconnection between notoriety and merit. Such a view crystallized in the 1960s with the publication of Daniel Boorstin's *The Image* (1961), which distinguished celebrity from heroism. In an argument that presaged more recent postmodernist theory on 'simulation and simulacra' and the implosion of artifice and reality (see Baudrillard, 1988), Boorstin argued that, with the growth of mass media, public relations, and electronic communication, it was possible to produce fame without any necessary relationship to outstanding action or achievement. Thus, the hero, whose fame is the result of distinctive action or exceptional, meritorious character, has been superseded by the celebrity, whose notoriety is manufactured by mass media without regard for character or achievement; the signs of greatness are mistaken for its presence. In Boorstin's definition, the celebrity is a 'human pseudoevent.' The phenomenon of celebrity is a symptom of a media-driven culture in which artifice has displaced reality, and in which merit and attention have become uncoupled. Although as Leo Braudy (1986) has shown, the oppositions between pure, 'real' fame and inauthentic 'artificial' celebrity do not fully hold up – historically, fame and merit have never been firmly and exclusively coupled – the conservative critical approach to celebrities as false, vulgarized heroes has pointed toward historically new features. Modern media, through the increasingly sophisticated creation, management, and reproduction of images, have an unprecedented capacity to place a person on the cultural radar screen, quickly and with no necessary reliance on the person's publicly celebrated actions or character. Thus the modern celebrity system does not require of celebrities that they be extraordinary in terms of achievement, talent, or character – some celebrity is 'acquired' and some 'achieved' (Rojek, 2001: pp. 16–18) – only that they provide engaging narratives, starring in what Neal Gabler (2001: p. 5) calls the 'life movie.'

Celebrities as Symbolic Entities

The interest shown by cultural critics in what the workings of contemporary celebrity tell us about the culture that makes it so central has been taken up in many humanities-based approaches to stars and stardom, which tend to consider the symbolic activity that takes place in and through celebrity discourse. Who gets attention, the logic goes, tells us much about the core values, or ideological contradictions, of the society giving the attention. In addition to the theme, noted above, that celebrities serve as ideological supports for capitalism and consumerism, two other themes have been particularly pervasive: the tension between egalitarian and aristocratic cultural strands; and the pursuit of the authentic self.

Celebrities as a Democratic Aristocracy

One striking feature of contemporary Western celebrity discourse is the way celebrities are treated to a cultural status that is simultaneously 'above' the rest of the populace and 'of' that populace. Celebrities are culturally constructed as a sort of elected aristocracy, both elevated and brought down by the watching crowds; the celebrity has become one symbolic means through which the population of the unfamous declares its own power to shape the public sphere (Marshall, 1997). Moreover, while celebrity culture certifies some people as more deserving of attention and rewards because of their difference from the rest of the population, it also continually demonstrates that such people are ordinary, just like everyone else (Braudy, 1986). Thus, popular celebrity discourse embodies ambivalence about hierarchy in Western democracies: celebrities are celebrated for being better than, but no better than, those who watch them.

The Search for the 'Real' Self

A second outstanding feature of contemporary celebrity discourse is the thematic emphasis on getting 'behind' celebrity images to the 'true' or 'real' self. Celebrity discourse, as Richard Dyer (1991: p. 135) has demonstrated, involves a 'rhetoric of authenticity': the question of what a celebrity is 'really like,' what kind of self actually resides behind the celebrity image, is a constant, whether in the form of tabloid exposés, behind-the-scenes reporting, celebrity profiles, or fan activities such as autograph seeking. In part, this is because celebrities have the unique characteristic of appearing to audiences only in media texts, while also living in the world as actual human beings – they are images, but are "carried in the person of people who do go on living away from their appearances in the media" (Dyer, 1991: p. 135). In part, the theme of realness is the result of the increasing visibility over time of celebrity production mechanisms, raising the question of whether the celebrity image has been manufactured to attract an audience, or

whether it reflects a true, deserving self (Gamson, 1994). Celebrity discourse, with its heavy rhetorical emphasis on authenticity, thus manifests a larger cultural anxiety about the relationship between media images and lived realities. This dynamic has been reworked and advanced in recent years through the genre of 'reality television,' in which celebrities purportedly show that they are real through the filming of their 'everyday lives,' and noncelebrities become famous for living their 'real lives' in front of the cameras (Grindstaff, 2010). Here, the exposure of the ordinary self – offered as a demonstration of authenticity – itself becomes a means to celebrity.

The Political Economy of Celebrity

While many of the attempts to grapple with the unique symbolic or ideological features of contemporary celebrity have been either entirely speculative or based exclusively on textual analysis, much of the empirical research on the topic has focused on celebrity as an economic and social system. Influenced by the strategies of political economists and organizational sociologists, this research has investigated not so much the cultural meaning of celebrity as the internal organization and economic logic of the celebrity system. In contrast to approaches that assume that film stars are popularly selected for attention, for instance, such analysts tend to see celebrity as the result of "the exigencies of controlling the production and marketing of films" (King, 1986: p. 155). Although celebrities increasingly emerge in other social domains (politics, academia, etc.), most attention has been given to the major celebrity production center, the entertainment industry (Currid-Halkett, 2010).

The Hollywood Star System and Beyond

The pursuit of celebrity, especially in the entertainment business, became highly routinized, rationalized, and industrialized over the course of the twentieth century, with the development of industries, such as public relations, specifically devoted to the generation and management of public visibility. Celebrities are, in this context, marketing tools. In the notoriously risky entertainment business, which requires high capital investment for most of its products, a star is an insurance policy against audience disinterest, used primarily to minimize the risk of financial loss. Thus, star images are typically managed in accordance with the needs of the financiers of the vehicle with which a celebrity is associated – with film stars, for instance, a movie studio. The key nexus is not so much the celebrity and his or her audience, but the celebrity's backers, who pursue publicity, and journalists, editors, and producers, who provide it (Gamson, 1994).

The structure of the star system has changed significantly over its brief lifetime. The early studio star system involved tight control of the production, exhibition, and distribution of films and their associated film-star images by several major studios; stars were under studio contracts, and studio publicity operations were responsible for producing and disseminating celebrity stories and images. When the studio oligopoly was broken up by a US Supreme Court decision in the 1950s, many more parties with a financial interest in celebrities' careers became involved in the management of celebrity images – personal publicists, managers, agents, in addition to the celebrity himself or herself, joined studio publicists in battling for control of the process. With the growth of television since the 1950s, the explosion of celebrity-driven media outlets since the 1970s, and the development and expansion of reality television since the 1980s and the Internet since the 1990s, moreover, it has become both easier to build celebrity and more difficult to retain it – hence Andy Warhol's famous declaration that eventually everyone will be world famous for 15 minutes. While Hollywood movie studios still generate a large proportion of American and international celebrities, celebrity has become less centralized, and the logic of celebrity has taken hold within a wider range of social spheres, including the worlds of literature (Moran, 2000), sports (Smart, 2005), politics (West and Orman, 2002), art, business, and academia, each with its own somewhat distinction celebrity production practices (Turner, 2004).

Celebrity Production in the Twenty-First Century

Recent history has seen some major changes in celebrity production apparatuses. Reality television, which developed in the 1980s in response to changing economic conditions in the television industry as a cheaper, quicker alternative to scripted programming (Collins, 2008), transformed celebrity production: no specialized training or prior experience was needed to enter the celebrity field, and celebrity became 'an outcome of a programming strategy' (Turner, 2004: p. 53). In addition, although in many ways the Internet simply extended the reach of existing entertainment industry organizations, it has also rapidly changed the dynamics of celebrity production, especially through Web 2.0 phenomena such as YouTube, Myspace, Twitter, and Facebook (Gamson, 2011; see also Rojek, 2012). As "the tools of self-publicity are increasingly available to ordinary people" (Bennett and Holmes, 2010: p. 76), barriers to entry to celebrity are reduced, and access to potential audiences does not require industry gatekeepers, celebrity production has become partly autonomous from the centralized, tightly controlled celebrity industry. The result of these changes was a large influx of 'civilians' into the celebrity field; forms of celebrity that are more fleeting, dispensable, and difficult to sustain than earlier ones (Collins, 2008; Currid-Halkett, 2010; Rojek, 2012), and the emergence of new celebrity types, such as the anticelebrity viral star (celebrated for being unlike conventional celebrities), the do-it-yourself celebrity (who has pursued fame outside the established celebrity system), and the microcelebrity (famous to a small community of fans) (Gamson, 2011).

Fandom and the Reception of Celebrity

Analyses of the social and economic organization of celebrity tend to bracket questions of its cultural meanings, and textual analyses of celebrity tend to operate with untested assumptions or assertions about the meaning and impact of celebrity for audiences. Methodologically, both have tended to exclude empirical research into the meaning of celebrities and celebrity in the everyday lives of the fans or audiences encountering

them. As the study of culture in general began, in the 1980s, to take more of a methodological turn toward audience research, audience-related aspects of celebrity have also come more sharply into focus. This territory remains, however, under-investigated, in part because the study of audiences is both methodologically cumbersome and costly.

Considerable thought, and a small but growing body of research, has been devoted to the question of the fans' or audiences' relationship to celebrities. One early theory, for instance, proposed that mass media such as television facilitate a 'parasocial relationship' between performers and audience members, in which the spectator comes to relate to the celebrity as if they were in a face-to-face relationship, with the 'illusion of intimacy' (Horton and Wohl, 1956). Since then, largely through psychoanalytic film theory, discussions have focused on the processes by which audience members identify with celebrities, especially film stars (Tudor, 1974; Stacey, 1991). Various typologies of identification have been set forth, emphasizing quite a range of activities, uses, and types of attachment developed by audiences in their encounters with celebrities (Marshall, 1997), with particular attention to celebrity gossip activities as 'fantasies of belonging' to a 'moral community' (Hermes, 1995: p. 132).

This has been especially important in challenging the assumption that 'the audience' for celebrity is a homogenous mass, and that celebrities mean the same thing for all of its members. Parasocial identification and celebrity hero worship, for instance, both appear to be common stances; but ironic, playful, and irreverent interpretations of celebrity images also appear to be prevalent, especially as the pursuit of celebrity itself has become a more common focus of public discussion (Gamson, 1994). Particular attention has been paid to the ways groups marginalized on the basis of race, class, gender, sexuality, ethnicity, nationality, or age make use of celebrity images for their own purposes: building group solidarity or expressing rebelliousness and alienation, for example, through the celebration of particular types of stars (strong women, for example, or stars from their own ethnic group) (Stacey, 1991). Finally, recent empirical work has detailed the meanings made by fans of particular celebrities (Vannini, 2004), celebrity fandom online (Soukup, 2006), teenagers' attitudes toward fame (Halpern, 2008), and interactional dynamics of encounters between celebrities and fans (Ferris and Harris, 2011).

The Future of Celebrity

While there is considerable consensus on certain distinctive features of contemporary celebrity, including its recent transformations, quite a bit of room remains for empirical investigations of the contours of celebrity as a socially organized system of meaning, status, identification, and pleasure; even with the growth of the 'celebrity studies' field in recent years, theory and speculation on the phenomenon remains more developed than empirical research. Considerable room remains, in fact, for a synthesis of the theoretical conceptualizations and explanations of celebrity culture, and subsequently for theory-driven empirical research that tests and refines those theories. Several areas in particular are likely to prove fruitful for future mixed-methods research. First, audience research can continue not only to document the range and types of audience positions vis-à-vis celebrities, but also to examine various possible explanations for the variance – audience characteristics, for instance, or qualities of different celebrity domains, genres, and types. Second, the process by which the logic of celebrity can and does spread to spheres other than entertainment, and how it may operate differently in those realms, is still not well understood. More systematic panel-data allowing comparisons across institutional domains are needed. Third, it remains the case that nearly all of the literature on celebrity has emerged from, and focused on, the United States and the United Kingdom. Cross-cultural comparative research is a very promising, and almost entirely untapped, source of insight into the cultural, economic, political, and social logic of celebrity. Finally, while it is clear that celebrity production has been transformed by digital technologies and new media – and presumably along with it the experience of celebrity for those encountering it – the contours and impact of these changes have yet to be fully documented, studied, and understood.

Censorship in Research and Scholarship

Nicholas G Evans and Michael J Selgelid, Centre for Human Bioethics, Monash University, VIC, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Censorship involves the suppression of communication that may be valuable or harmful to the censor, the individual or group censored, or the intended recipient of the communication. Researchers and scholars have been censored throughout history by religious, political, military, and corporate powers. During the twenty-first century, much debate has surrounded questions about the potential censorship of 'dual-use' biological research that could enable production and use of biological weapons. Whether or not censorship would be ethically appropriate in this contemporary context depends on how trade-offs should be made between the values of free communication and harm prevention.

Censorship involves the intentional suppression of communication in order to prevent dissemination of information that may be valuable or harmful to the censor, the individual or group censored, or the intended recipient of the communication. Within debates about censorship one finds a range of definitions, which may be so expansive as to include any act of restricting information flow, or so narrow that only the suppression of expression by the state or one of its proxies is encompassed. Broad definitions will include – and narrow definitions will exclude – what should arguably be considered gray-area cases of censorship, such as legislation not aiming at suppression of speech that nonetheless causes individuals to suppress themselves through fear of legal action (Schauer, 1978). The diversity of definitions has lead some to suggest that censorship falls on a spectrum with other acts that restrict speech or are otherwise more or less *like* censorship (Alexander, 2005).

What binds these definitions together is a set of exemplar cases that inform a well-understood paradigm of censorship. Paradigmatic censors include government authorities, militaries, and religious institutions; more recently, corporations have engaged in censorship and self-censorship (that is, suppressing their own communication) to protect their interests. Researchers and scholars are often vulnerable to censorship by these powerful actors, whose power depends on a particular orthodoxy. The history of research and scholarship is thus replete with examples involving the abuse of power in the suppression of work that challenges established knowledge or practice.

Cases of Censorship: History, Methods, and Motivations

The censorship of research and scholarship has a long history, but its early roots lie in the suppression of the dissemination of knowledge by religious authorities. Charges of heresy – the crime of speaking contrary to church orthodoxy – have been used to justify censorship of priests and laypersons for hundreds of years. A prominent example of this is that of Peter Abelard, a fourteenth-century Catholic scholar accused of heresy for attempting to interpret the Catholic Trinitarian doctrine along rationalistic lines. Abelard, found guilty of this alleged heresy, was required to burn his works and forbidden to preach (Godman, 2000). Paradigmatic of religious censorship, Abelard's trial also demonstrates some of the iconic means of achieving censorship: legal sanction, destruction of works, and formal silencing under threat of further punishment.

The Catholic Church is best known for its censorship of works listed on the *Index Prohibitum Librorum*, or 'Index of Prohibited Books,' including those of Denis Diderot, John Stuart Mill, and George Berkeley. The works of Nicolaus Copernicus and Galileo Galilei, whose research spurred the scientific revolution, also once occupied the list. Copernicus' *De Revolutionibus Orbium Coelestium* (On the Revolutions of the Heavenly Spheres) forwarded the claim that the earth orbited the sun, contesting the Aristotelian cosmology of the day, that situated the earth as the immobile center of the universe. *De Revolutionibus* was initially published openly. The controversy surrounding *De Revolutionibus* was initially not forthcoming, and the work was published openly. The reason for the lack of controversy surrounding Copernicus' *De Revolutionibus* was partly due to the disclaimer provided in the preface by Osiander, Copernicus' student, added after his teacher's death. While Osiander's motives remain unknown, his claim that *De Revolutionibus* was "not put forward to convince anyone that [Copernicus' theories] are true, but merely to provide a reliable basis for calculation," effectively silenced the intent of Copernicus' work. By subverting the intent of Copernicus' work–the preface was not signed, so it appeared to be Copernicus' own thoughts on his work–Osiander accomplished something that might well be considered equivalent to censorship in outcome (Henry, 2012).

De Revolutionibus was finally censored by the Church in 1616, following the release of Galileo's *Sidereus Nuncius* (The Sidereal Messenger). *Sidereus Nuncius* provided… a further challenge to Aristotelian cosmology through Galileo's telescopic observations of a changing, imperfect cosmos, including a cratered moon and impermanent, moving stars (Tolbert, 2003). While on its own, *De Revolutionibus* was initially deemed harmless; but when placed alongside *Sidereus Nuncius* it became a threat to Church doctrine. Works subjected to censorship may only demonstrate the qualities that make them targets of censorship years – even decades – after the fact.

Galileo's *Dialogo sopra i due massimi sistemi del mondo* (Dialogue Concerning the Two Chief World Systems), however, caused controversy almost immediately. In *Dialogo*,

Galileo defended his heliocentric conception of the solar system, and presented a strong challenge to the orthodox view that placed the earth – and thus man – at the center of the cosmos. *Dialogo* was initially well received by Pope Urban, with one caveat: Urban requested that Galileo include a disclaimer on the subject of the reciprocal motion of the tides, which Galileo (wrongly) believed was due to the movement of the earth around the sun. Urban noted that although Galileo's argument was convincing, it was still possible that God had designed the system of the tides to appear that way, while still being controlled by some other, divine means. Galileo did incorporate these remarks; but by presenting the Pope's views through the voice of the dullard Simplicius, he insulted the Church, bringing about his censorship and house arrest (Miller, 2008).

Orthodoxy may be central to censorship motivated by religious conviction, but the political process can play a strong part in the practice of censorship. The Butler Act of 1925, for example, is an example of censorship in which the State Government of Tennessee passed a bill that rendered it unlawful to teach evolution, or any other material that denied the Biblical account of the origin of humans and sought to account for human existence as ancestors of 'lower' animals (House Bill 185, 1925). The Butler Act was motivated by religious belief, and a desire to deny evolution in favor of creationist arguments, but relied on legal means to deter teachers from disseminating information. As with the trial of Abelard, legal injunction, or its threat, is often a powerful method of censorship. In case of the Butler Act, it is also important to note that preventing dissemination of scholarship by censoring teachers is a powerful way to prevent research or scholarship from achieving recognition in the public eye.

The persecution of Soviet scientists by Trofim Lysenko, director of the Institute of Genetics within the Soviet Academy of Sciences from the 1940s through to the 1960s, is one of the most horrific examples of modern censorship of science. Lysenko advocated a theory of heredity that posited that organisms inherited traits from the surrounding environment, in contrast with the Mendel–Morgan gene theory that supported the idea that the transmission of genetic information from parents to offspring influenced the traits of an organism. As director of the Academy of Sciences, and friend of Joseph Stalin, Lysenko embarked on a campaign to ensure the supremacy of his theory by imprisoning those who held competing theories. Lysenko's reasoning, at the time, was that other theories weakened the Soviet State, and threatened Soviet agriculture. During his reign, Lysenko imprisoned and killed thousands of scientists who held theories of genetics that conflicted with his own. Lysenko's actions are believed to have set back Soviet biology by decades, demonstrating the extent of the harms that can be inflicted through the abuse of power by a censor (Joravsky, 1986).

Militaries have often sought to censor research that might provide an adversary with some advantage: as early as 1792, the French military restricted access to technology and research on improving artillery (Gillispie, 1992). In World War II, science and technology became deciding factors in the war effort, and the censorship of research became part of both Allied and Axis strategy. The Manhattan Project, which led to the development of the first two atomic weapons, was perhaps the ultimate example of this practice: an entire community of scientists and their families were veiled behind a wall of secrecy and censorship in the name of a wartime scientific endeavor.

Following World War II, the control of science and technology to achieve nuclear supremacy led to the *Atomic Energy Act* in the United States. The Act presumptively restricted access to "(1) [the] design, manufacture, or utilization of atomic weapons; (2) the production of special nuclear material [uranium-233, uranium-235 or plutonium in their natural or enriched states]; or (3) the use of special nuclear material in the production of energy" (AEA, 1946: pp. 1–15). This policy, known as the 'born classified' doctrine, is almost unique in liberal Western democracies, and is certainly the only one of its kind in the censorship of science (Quist, 1994).

Science is now big business, and companies with vested interests may engage in censorship and self-censorship in order to maintain their advantage in the market or prevent damage to their reputations. The tobacco industry, for example, has engaged in a sustained campaign to obfuscate, avoid, and outright suppress research on the health risks of smoking. Phillip Morris and British American Tobacco, for example, engaged in the practice of self-censorship of research associated with the health risks of smoking, and of second-hand smoke. Lawyers employed by these companies would review both in-house research and externally commissioned research for its potential to cast smoking in a negative light. Results and publications that posed such risks were rewritten to provide weaker or alternate conclusions, and at times were completely suppressed. By placing themselves in a position where they could censor research on the risks of smoking, tobacco companies were able to control and suppress information that might show smoking to be harmful, thereby manipulating scientific consensus and policy-making (Glantz et al., 1996).

Current Issues: The Dual-Use Dilemma

In the twenty-first century, the censorship of research has been suggested as a possible regulatory strategy in addressing the *dual-use dilemma*, which arises when one and the same piece of research can be used to benefit or harm humanity. A paradigmatic case of dual-use research occurred in 2001, when Australian virologists modified the mousepox virus genome. The (unexpected) outcome of this research was the creation of a virus that killed mice that were genetically resistant to, and mice that had been vaccinated against, ordinary mousepox. Mousepox is genetically similar to smallpox, a disease that killed hundreds of millions of people in the early twentieth century; and, supposedly, more people than any other infectious disease in recorded history. Critics fear that publication of the mousepox study might enable bioterrorists to create and unleash a strain of vaccine resistant smallpox (Miller and Selgelid, 2008).

A 2004 report by the National Academies of Science, *Biological Research in an Age of Terrorism*, considered the possibility of censoring dual-use research posing serious risk of misuse. The report (known as the 'Fink report' after its chairperson, Gerald Fink) concluded that any suppression of potentially

dangerous research results should be left to voluntary self-governance of scientists (NRC, 2004). On the advice of the Fink report, the National Science Advisory Board for Biosecurity (NSABB) was created with the aim of providing guidance on the governance of dual-use research. In June 2007, the NSABB released its initial guidance, including a 'responsible communication' plan for federally funded research with dual-use potential. This plan, in line with the Fink report, relied on self-governance of scientists and, in particular, the discretion of principal investigators (NSABB, 2007).

The model of self-governance has, however, been challenged. In 2005 two researchers at Stanford University modeled a terrorist attack distributing botulinum toxin through a cow-to-consumer milk supply, using parameters taken from the United "States" milk supply. The study demonstrates how 10 g of botulinum toxin, distributed prepasteurization, could result in the death of 200 000 people. These deaths would be concentrated, the researchers argued, among child populations, as milk is distributed regularly outside of normal channels to schools in the United States, and the youth and low body mass of children makes them more susceptible to botulinum toxin poisoning (Wein, 2009: p. 803).

The dual-use potential of this research prompted the Department of Health and Human Services to request the *Proceedings of the National Academies of Science* (PNAS) to withhold publication of the study (Simonson, 2005; Wein and Liu, 2005: pp. 9987–9988). The PNAS embargoed the article for a week, before publishing it with an accompanying editorial by Dr Bruce Alberts, editor in chief of the PNAS, claiming that the scientific process required openness to improve human health, and that the research should be published to better assist in this aim (Alberts, 2005).

In 2011, Ron Fouchier, a virologist from Erasmus University in the Netherlands, announced that he had successfully created a strain of H5N1 avian influenza that was transmissible between ferrets inhabiting the same cage. Ferrets are a well-known analogue for human immune responses to influenza viruses, and their proximity showed that this variant was airborne transmissible in mammals – something not seen in wild H5N1. Fouchier – together with Yoshihiro Kawaoka of the University Wisconsin, who completed similar research that same year – claimed that this research showed that bird flu, a virus with a reported fatality rate of up to 60% in humans, could become transmissible between mammals – a recipe for a potentially devastating pandemic.

The purported benefits of this H5N1 influenza research include raising awareness about the risks of emerging influenza viruses, assisting in disease surveillance, and advancing influenza research (e.g., vaccine development). Yet concerns about the potential danger of this research, either through accidental or intentional release of the engineered virus, prompted the NSABB to recommend the partial censorship of the research (i.e., via omission of detailed description of materials and methods). However, the NSABB later recanted in response to revisions (providing further explanation of the purported public health benefits of the studies) made to the submitted papers by the researchers (Evans, 2013).

The NSABB's policies were reevaluated in 2012 in response to the H5N1 avian influenza studies. The United States Government released new policy regarding the regulation of state-sponsored dual-use research of concern, outlining an assessment procedure for use in assessing the dual-use character of government-sponsored research and determining the capacity research possesses for misuse. In cases where the risks posed by the research cannot adequately be mitigated, federal departments and agencies were instructed to determine whether it was appropriate to:

1. Request voluntary redaction of the research publications or communications.
2. Classify the research:
   a. In accordance with National Security Decision Directive/NSDD-189, departments and agencies will make classification determinations within the scope of their classification authorities and appropriate classification guidelines or may consult with other departments and agencies to make these determinations.
   b. Departments and agencies may consider whether to refer classified research to another department or agency for funding.
3. Not provide or terminate research funding (Office of Biotechnology Activities, 2012).

These regulations represent the first known policy that actively makes possible the censorship of dual-use life sciences research not already restricted by virtue of being classified research, as in the case of nuclear research.

The Ethics of Censoring Dual-Use Research

Dual-use research provides a backdrop from which to understand the ethics of censoring research and scholarship. Censorship is, on the face of it, a violation of an individual's right to freedom of speech (which tends to incorporate publishing, among other forms of communication), widely recognized and justified through appeal to a plural set of values. Protecting freedom of speech allows us to communicate, negotiate, and satisfy our preferences; and speech can be desirable in itself (i.e., free speech promotes utility). Speech is an exercise in individual self-determination or autonomy. Autonomy is valuable to an individual's quality of life, and a self-governing citizenry is important to a well-functioning liberal democratic society. Protecting speech assists in securing equality between individuals by ensuring everyone has sufficient opportunity to participate within a society. Finally, preventing interference in the activities of individuals necessarily promotes freedom, which may be seen as a good in itself (Alexander, 2005).

Yet few commentators hold that all speech promotes these values (and is thus deserving of protection as a matter of right); moreover, at times the right to freedom of speech may be outweighed by competing considerations even if speech is still valuable (other things being equal) (Waldron, 2010). Even the most extreme of libertarian thinkers, such as Robert Nozick, acknowledge that there are some (exceptional) cases where rights might be outweighed by competing considerations (Nozick: p. 30). The right to freedom of speech is valuable, but it is not always the only or most valuable thing to promote. In cases of conflict, a balance should be struck between free speech and other values (Selgelid, 2007).

Censorship is commonly considered permissible in cases where the dissemination of information may lead to immediate and/or catastrophic harm. Dual-use research, in particular, raises this possibility. The concern that the information disseminated in scientific publication will enable acts of bioterrorism lies at the heart of the dual-use dilemma in the biological sciences. In the mousepox example above, the concern was the possibility of similar modification of the smallpox virus, which in its wild form killed hundreds of millions of people during the twentieth century. The botulinum toxin studies modeled an attack that could kill approximately 200 000 people, using relatively small amounts of the toxin. In the case of the H5N1 avian influenza studies, wild H5N1 has a case-fatality rate of 60% in humans. Modifying the virus so that it was transmissible between humans could cause a catastrophic loss of life – the 1918 'Spanish flu' pandemic killed somewhere between 20 and 100 million people, but had an average case-fatality rate of approximately 2.5% (Taubenberger and Morens, 2006).

Moreover, nuclear science arguably provides a precedent for censoring research with immensely destructive potential. Research on the first atomic bombs – which, combined, killed approximately 300 000 people – was censored vigorously. Many atomic scientists accepted this practice (though not without complaint) (Rhodes, 1986). Given sufficient evidence of the likelihood that a devastating biological attack could occur, censorship of contemporary dual-use life science research might arguably be appropriate (at least in exceptional circumstances). A consensus in debates about dual-use life science research is that an appropriate balance should be struck between the goals to promote scientific progress, on the one hand, and security, on the other. What an appropriate balance would be, however, remains an open question (Selgelid, 2007; Evans, 2013).

Beyond the right to freedom of speech, there are other reasons that have been given for protecting the publications of researchers and scientific publications in particular. None of these reasons gives an absolute justification for open communication of science, but they can be incorporated into the considerations of value described above. First, scientific freedom and openness are essential to the structure of science by providing a forum within which ideas can be examined, reviewed, and critiqued. If there is little prior knowledge of where innovative and beneficial research will arise, maximizing openness maximizes the chance of reaping the benefits of new research (Resnik, 2008).

Not all agree, however, that this is sufficient reason to protect scientific speech. Significant effort is put into funding allocation to decide which projects and scientists will produce the best results. Though subject to critique, these systems show that research is planned and funded with certain expectations about where beneficial research will occur. If such judgments are appropriate in decision-making about what science should be done, the argument goes, why should they not also play a role in decision-making about what research will be published? There is a clear trade-off between security and scientific progress, but neither is typically held to be absolutely important (Evans, 2013).

Some claim that the institutional function of a university is to produce and disseminate knowledge. Research and scholarship conducted at universities, therefore, should perhaps be protected in virtue of the moral purpose of the institution of the university. Interfering with this function would not only violate the rights of researchers, but arguably also pervert the purpose of the university (Miller, 2010).

Others have noted, however, that the interference of private funding bodies, government agencies, and companies into the research affairs of universities can pervert their course *even if knowledge results* (Elliott, 2010; Evans, 2013). Thus, the function of a university is not sufficient reason to argue against interference, but merely to argue against certain kinds of interference – e.g., such as that of Lysenko and tobacco companies. Whether censorship of dual-use research would be an unacceptable kind of interference, however, is debatable.

Finally, there are pragmatic considerations about the practice of censorship, and what they mean for research and scholarship. As the history of censorship demonstrates, censorship is a practice that is either indicative of, or prone to, egregious abuses of power. Even if there are good reasons to censor science in some cases, there is still some risk that the censorship process would be perverted by powerful interests. The Soviet scientists persecuted under Lysenko are the most extreme example of the horrors that can be inflicted against scientists; less violent, but still troubling, is the suppression of public health research by tobacco companies.

Even the *Atomic Energy Act*, in which research was censored out of concern about the security risks of nuclear science and technology, has been used inappropriately. Empowered through the *Atomic Energy Act*, the Atomic Energy Commission wielded extensive power that it abused to promote its own interests as well as those of the people it served. Famously, this power was wielded against J. Robert Oppenheimer, the former director of the Manhattan Project, in depriving him of his security clearance and exiling him from the classified nuclear community.

Numerous aspects of Oppenheimer's trial arguably involved abuses of power. There was a well-known vendetta between Lewis Strauss, chairman of the Atomic Energy Commission, and Oppenheimer. There was also the background hysteria about communism, and Oppenheimer's past – a past that he lied about during security proceedings – included association, though not formal affiliation, with the Communist movement. The US Air Force, moreover, desired the construction of large, strategic nuclear weapons, a program that Oppenheimer publicly opposed. Oppenheimer's trial serves as a reminder that personal grudges, ideological disputes, and political maneuvering can all be used to pervert a process designed to ensure the security of a people (Bernstein, 1982).

Conclusion

Any further debate about the ethics of censoring research and scholarship will ultimately turn on the weight of the factors discussed above: the balance of values in particular acts of speech; the design, function, and operation of social institutions; and the practical difficulties associated with censorship, which has a murky history. Censorship of research and scholarship is, like the censorship of any speech, ethically fraught. It is, however, a source of contemporary debate as the technologies that stem from scientific research become the potential tools of terrorists. Though considerable uncertainty remains

about how best to weigh the values implicated in the dissemination of research findings against the harms of the misuse of biotechnology, there is wide agreement that the right to freely disseminate research is neither absolute, nor always top priority.

Census Microdata

Steven Ruggles, University of Minnesota, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Census microdata provide individual-level information describing the characteristics of persons, families, and households. Compared with conventional aggregate-level census data, microdata offer several advantages, including the ability to customize tabulations, construct new variables based on combining characteristics of family members, conduct individual-level multivariate analysis, and make data comparable across time and space. Limitations of census microdata vary depending on the source, but include suppression of detailed information to ensure confidentiality, limited sample size, and the need for specialized statistical software. Census microdata have existed since the 1960s, but vast new data sets are becoming available for social science research.

Definition of Census Microdata

Census microdata consist of individual responses to census questionnaires, coded into a form suitable for statistical analysis. The term census microdata refers to responses from both complete censuses and from large-scale household surveys conducted by statistical agencies, such as the American Community Survey for the United States or the *Mikrozensen* (Microcensus) for Germany. Census microdata are among the most widely used sources in the social sciences.

Publicly accessible census microdata are usually samples of both individuals and households. With a few exceptions, records describing individuals are nested within families and households, and the data provide information about the interrelationships of the members of each residential group. The samples are typically large; most include at least 1% of the population and the most common sample densities are 5 or 10% of the population. Complete microdata including all enumerated individuals in a population are sometimes available for historical populations or through restricted-access data enclaves.

Most census microdata include information on economic activities, ethnicity, educational attainment, fertility, migration, marital status, and consensual unions. In developing countries, most censuses provide information about mortality and disabilities, and there are often extensive housing characteristics, usually including water supply, sewage, and physical characteristics of the dwelling such as materials used for the floor and roof.

The availability of census microdata is growing rapidly. In 2000, publicly accessible microdata were available for just five countries, and included data on fewer than 100 million individuals. By 2013, census microdata were freely available for 700 censuses and surveys of 78 countries, which collectively provide data on 750 million persons residing in 200 million households. As shown in **Figure 1**, it is estimated that the total will grow to approximately one thousand million records from 100 countries by 2018 (Ruggles, 2014).

Advantages and Limitations of Census Microdata

Advantages

Until recently, most census statistics were available only in aggregated form. Whether disseminated in books of statistical tables or in machine readable form, these data were designed to describe the characteristics of administrative units (such as states, counties, or municipalities) or statistical units defined by the census agency (such as census tracts or block groups). Unlike aggregated census data that provide characteristics of *places*, microdata provide the characteristics of *people*. This allows investigators to pursue powerful research strategies.

- Tabulations customized to particular research questions. For example, suppose one wants to study the relationship of teen marriage to high school dropout rates. The US census never published a table on marital status by school enrollment by age, so that topic cannot be investigated using the aggregated census data. With microdata, however, investigators can analyze any combination of characteristics.
- Customized variables based on multiple records. Because of the hierarchical structure of the microdata – individuals are organized into families and households, and the interrelationships of the individuals are known – microdata make it possible to develop new measures that combine characteristics of more than one person. For example, by comparing a husband's ethnicity with that of his wife, one can measure ethnic intermarriage. Investigators can develop a virtually limitless number of customized measures that combine characteristics from multiple persons, such as number of own children attending school, age differences of siblings, or coresidence of kin.
- Multilevel multivariate analysis. Investigators can move beyond the simple three-way or four-way tables provided by aggregate census data and control for many individual, family, and community-level variables simultaneously using multilevel multivariate techniques.
- Comparability across time and space. Aggregated tables are often difficult or impossible to compare across time or between countries. If an investigator is interested in studying trends on high school dropout rates in the United States during the 1980s, the aggregate census tables are of little use. The 1980 census provides information on school enrollment for the age groups of 14–15 and 16–17, whereas in 1990 the age groups were 10–14 and 15–17; the incompatibility of the age groups means we cannot compare dropout rates over time. Microdata make the comparison simple, since school enrollment at every age can be easily calculated.

Figure 1 Number of individual cases of census microdata readily accessible for research. Source: Ruggles, S. Big microdata for population research. Demography, 51, 287–297.

Limitations

Despite the power of microdata, there are three limitations that make preaggregated data preferable for some applications.

- Limited detail. In some countries – particularly in Europe and North America – privacy concerns limit the geographic detail available in the publicly accessible census microdata. In the United States, for example, only places of 100 000 population or greater can be identified. This means that analyses of small geographic areas, such as neighborhoods, the only potential sources are aggregated data or restricted-access microdata. Beyond geography, a few countries suppress other key information commonly needed for demographic analysis. Several countries, group age into 5-year groups. In a few countries, such as the Netherlands, the individual records are not grouped into families and households, greatly compromising the utility of the data. These limitations tend to be substantially less severe outside of the most-developed countries, and older historical microdata generally provide full detail on all variables.
- Limited sample size. Census microdata provide many more cases than most other forms of social and economic microdata; most census microdata samples include hundreds of thousands or millions of observations. Nevertheless, the sample sizes are sometimes inadequate for studying small geographic areas or small subpopulations; in these cases, aggregated data or narrowly focused surveys may be the only alternatives.
- Need for specialized analysis software. Unlike published tabular statistics, use of microdata traditionally has required specialized statistical software packages. These packages – such as SPSS, SAS, and Stata – are complicated, expensive, and demand substantial computing power. Online data analysis tools are beginning to mitigate this constraint.

Census microdata may also be compared with small-scale demographic survey data, such as the Demographic and Health Surveys widely used for studying conditions on the developing world. Such surveys generally have more comprehensive subject coverage than censuses, and data quality is usually high. Sample sizes are comparatively small, however, and they are usually clustered, limiting the potential for spatial analysis. Census microdata samples are usually an order of magnitude larger than demographic surveys. Although some census data are unreliable, overall nonresponse rates compare favorably with sample surveys. Census microdata can be used fruitfully in conjunction with surveys to provide information about local context that cannot be generated from the surveys themselves.

Origins and Development of US Census Microdata

1960s and 1970s

The first census microdata was created as a byproduct of the 1960 US census (U.S. Bureau of the Census, 1964). The expansion of social science research in the late 1950s and early 1960s had led to growing demand for special tabulations designed to answer specific research questions. The Census Bureau prepared these special tables on a reimbursable basis, but the costs were high; the Census Bureau typically charged $5000 for a basic tabulation project at a time when the average annual salary of a US social scientist was just a little over $7000 (Kraus, 2011; Ruggles et al., 2012).

To meet the demand for customized tabulations, in 1962 the Census Bureau drew a 1-in-1000 extract of the basic data tapes they had used to create tabulations for the published census volumes. To preserve confidentiality, the Census Bureau removed names, addresses, and other potentially identifying information. The Census Bureau made the data available to the research community on 7 IBM tapes or 11 UNIVAC tapes for a charge of $1500 (Brunsman, 1963; Duncan and Shelton 1978; Hauser, 1960). Only a few research centers had access to computers, so the Census Bureau also made a 1-in-10 000

version available on 18 000 punch cards that investigators could analyze using older unit record machines (Mason et al., 1977; U.S. Census Bureau, 1964).

The 1960 public use sample revolutionized analysis of the American population and led to an explosion of new census-based research. It allowed researchers to make tabulations tailored to their specific research questions. As Otis Dudley Duncan put it,

> The importance of this innovation can hardly be overestimated. We have known for a long time that certain essential social indicators are available in principle from the Federal statistical system. Yet all too often efforts to put information into an appropriate form are frustrated by the inadequacy of the published summary tables for the purpose at hand. With access to the unit records, the social scientist may specify in detail how variables are to be manipulated so as to produce an optimal estimate of the magnitude desired.
> Duncan, 1974: 5097

Mason et al. (1977) concurred, explaining that the 1960 census microdata sample was a 'development of profound significance to social research' because it gave the research community 'freedom to retabulate or manipulate without the constraints imposed by a fixed set of printed volumes.' Not only did the new sample allow researchers to make tabulations tailored to their specific research questions, it also allowed them to apply new methods – such as individual-level multivariate analysis – to the analysis of census data.

Despite its high impact, the initial 1960 sample had two serious limitations. First, the sample density was small. The one-in-1000 sample density yielded about 180 000 person records. Given the modest capacity of computers in 1964, this was a substantial number of cases. Nevertheless, as researchers began to use the sample for detailed analyses of small population subgroups, however, its limitations became apparent. Second, the 1960 public use sample provided little geographic information. To ensure confidentiality, the Census Bureau stripped off all information on places below the state level. This meant, for example, that it was impossible to extract a subsample of the New York City population.

Both of these problems were addressed by the 1970 public use samples. The Census Bureau expanded the size of the 1970 samples more than 60-fold compared with the 1960 sample. The Census Bureau provided six independent public use samples for 1970, each of which had a one-in-100 density. Users who required an exceptionally large number of cases could combine the samples to obtain six-percent sample density, or about 12 million person records. In addition, the 1970 samples provided a variety of alternate geographic codes, although the Census Bureau still did not identify places of less than 250 000 population (U. S. Census Bureau, 1972).

In 1972, the Center for Research Libraries obtained funding from the National Science Foundation to make a new version of the 1960 sample. The new version enlarged the sample density from one-in-1000 to one in-100, and at the same time reorganized the coding schemes and record layouts to be compatible with the samples from 1970 (U.S. Census Bureau, 1973). This compatibility made it relatively easy for investigators to pool data from 1960 to 1970 and thus incorporate change over time into their analyses, and this became a widespread research strategy. The public use samples for 1960 and 1970 quickly became essential tools of American social scientists. In the mid-1970s, demographers Samuel Preston at the University of Washington and Halliman Winsborough at the University of Wisconsin independently developed projects to extend the series backward by creating new historical samples of earlier censuses.

1990s

By 1991, there were national census microdata samples available for eight US censuses: 1880, 1900, 1910, 1940, 1950, 1960, 1970, and 1980. A ninth census year – 1990 – was planned. For the first time, the potential existed for individual-level national studies of long-run social and economic change, but in practice, such analysis was cumbersome. The nine samples resulted from separate projects headed by four different investigators and six different performance sites. Even in the few cases where the same investigator working at the same location created samples for more than one census year, there were often incompatibilities, even if there was a recognizable family resemblance. For example, the two Winsborough samples (1940 and 1950) use completely different record layouts and have different coding schemes for many variables, including occupation, institution type, citizenship, and employment status. As noted, the Census Bureau samples for 1960 and 1970 were largely compatible with each other. The 1980 sample, however, was completely different, and offered substantially greater detail than did 1960 or 1970 (U.S. Census Bureau, 1982).

The Integrated Public Use Microdata Series (IPUMS) was launched in 1992 to reconcile the differences among the eight US census microdata samples. Using structured data-integration metadata, IPUMS implemented a system of consistent codes across census years without losing information, and provided comprehensive integrated documentation highlighting comparability issues. IPUMS began disseminating integrated microdata through the Internet in 1993. The database now includes microdata from every US decennial census from 1850 forward, as well as Census Bureau microdata from the Current Population Survey and the American Community Survey. In 1995, IPUMS introduced Web-based data access technology that allowed investigators to design customized data sets incorporating microdata from multiple sources, greatly simplifying access to large-scale microdata (Ruggles, 2005).

International Census Microdata

Despite the success of large-scale US microdata, statistical agencies in other countries were slow to create similar resources. A few national statistical offices – including those of Australia, Brazil, China, Colombia, Mexico, Norway, and South Africa – made internal microdata available to selected academic researchers on a case-by-case basis. Several organizations developed substantial archives of census microdata from multiple countries for comparative research, but they were unable to provide access to off-site researchers.

Statistics Canada began producing Public Use Microdata Files (PUMF) in 1974, and the United Kingdom created Samples of Anonymized Records (SARs) in 1993. In both these cases, the samples were very small, confidentiality edits compromised usability for many applications, and access was difficult for researchers from other countries. Notwithstanding these limitations, the PUMF and SARs have been successful, and they rank among the most important sources for demographic research in Canada and the United Kingdom.

Most countries have had no systematic program for preservation or reuse of census microdata once the statistical agency had published summary tables. As a result, most machine-readable census microdata from the 1960s and 1970s had already disappeared by the mid-1990s, and large portions of the surviving microdata was at immediate risk of destruction.

Robert McCaa, a historical demographer at the University of Minnesota, led an effort to liberate and preserve the world's census microdata. From 1998 to 2013, McCaa recruited 100 national statistical agencies around the world to collaborate with the IPUMS project (**Figure 2**); perpetual agreements with each country ensure long-run preservation and free access for the academic community (Minnesota Population Center, 2013).

By 2013, IPUMS had released anonymized integrated microdata samples for 238 censuses of 74 countries taken between 1960 and 2011. These 74 countries have more than three-fourths of the world's population. Most of the countries outside of Western Europe and North America provide good geographic precision, identifying places with as few as 20 000 residents. For 63 countries, IPUMS provides microdata from multiple census years (3.6 census years per country on average). The samples are usually large: almost two-thirds of the samples include 10% or more of the population, and 85% of the samples include at least 5%. Taken together, the 238 samples currently available include information on 544 million individuals; by 2018 the IPUMS project expects to have released data for about 800 million persons drawn from 300 censuses of about 100 countries.

Census Microdata from Genealogical Sources

Since 2000, the availability of historical census microdata has expanded rapidly through the adaptation of genealogical data to meet scientific purposes. Starting in 1982, the genealogical arm of the Church of Jesus Christ of Latter-Day Saints – known as FamilySearch – organized an army of 25 000 volunteers to transcribe information stored on microfilm images of the 1880 US census and the 1881 censuses of Britain and Canada. When the work was complete in the late 1990s, FamilySearch provided copies of digital census transcriptions describing 84 million persons for academic use. These data became the centerpiece of a new international collaboration to develop integrated complete enumerations of the North Atlantic region suitable for scientific research. The North Atlantic Population Project (NAPP) began in 1999 with participants from Britain, Canada, Iceland, Norway, and the US. The scope of the collaboration has grown over the past decade to include universities and national archives in Denmark, Egypt, Ireland, Mexico, and Sweden. Each year, more censuses are added, and NAPP presently disseminates data on 130 million persons drawn from 33 censuses of nine countries enumerated between 1703 and 1930 (Ruggles et al., 2011).

Over the coming 5 years, the quantity of accessible historical microdata will increase by an order of magnitude, to 1.1 billion individual records. Most of this results from collaborations of academic researchers with large genealogical organizations, including the two leading commercial vendors of genealogical

Figure 2 Countries participating in Integrated Public Use Microdata Series-International. Disseminating means that microdata were being disseminated as of June 2013. Participating means that the statistical agency has joined the partnership, and microdata will be available soon. Source: Minnesota Population Center, 2013. Integrated Public Use Microdata Series, International: Version 6.2 [Machine-readable Database]. University of Minnesota, Minneapolis.

data, Ancestry.com and findmypast.com. New data products will include the entire censuses of Great Britain from 1851 to 1911 (a net addition of 175 million person records) and complete census microdata covering all enumerated persons in the United States from 1790 to 1940 (a net addition of 730 million person records).

With a few comparatively small exceptions, the historical data are transcribed from public sources and there are no confidentiality restrictions. This means that the historical data sets ordinarily provide full information on geographic location. The historical data sets also include names, although to protect commercial interests of the commercial partners, there are restrictions on the dissemination of names for the data sets donated by genealogical organizations. Nine countries have multiple complete enumerations with full identification, allowing investigators to trace individuals and households over the life course and across several generations. The data will be freely disseminated through IPUMS.

Restricted Census Microdata

The Census Research Data Centers (RDCs) operated by the US Census Bureau's Center for Economic Studies house complete decennial census microdata for 1970 through 2000, including both short-form and long-form records. Thanks to a recently completed project to restore the 1960 census, complete long-form data covering 25% of the 1960 population are now available through the RDCs (Ruggles et al., 2011). The RDCs also house complete American Community Survey data covering 47 million persons, and are adding about 5.4 million persons per year. In all, the microdata housed in the RDCs currently describe 1.05 billion persons with full geographic identification down to the block level. The Minnesota Population Center is currently converting these data to IPUMS format.

The Minnesota Population Center is developing an international restricted data enclave modeled on the Census RDCs to provide access to about 130 complete census enumerations with full geographic detail. These data provide information on approximately 1.6 billion persons. Like the Census RDC, no restricted data will ever leave the secure servers; instead, the enclave will provide remote access through virtualization. All results will be assessed for potential violations of confidentiality, and the data enclave staff will email them to the researchers only after they are cleared (Ruggles, 2014).

New Applications of Census Microdata

Researchers will soon have access to data spanning two centuries for some North Atlantic countries and the last two to five decades for much of the rest of the world, allowing direct observation of demographic and economic transformations that are reshaping society. Key research topics include residential segregation; migration and migrant settlement patterns; urban sprawl; the economic and ideational context of declines in fertility, mortality, and intergenerational coresidence; rural depopulation and agricultural consolidation; the identification of concentrated poverty; causes and levels of change in ecosystems as a function of human–environment interactions; comparative cross-national policy analysis; and multilevel analysis of the impact of community characteristics on individual behavior.

Variation in economic development and demographic behavior creates opportunities to assess the impact of local characteristics on individual behavior, thereby offering the potential for understanding the consequences of both structural and ideational change. For example, Esteve et al. (2012) examined the rise of cohabitation for 350 regions of 13 Latin American countries over four decades, and assessed the impact of national and regional conditions on the pace of change.

The large scale of census microdata enables study of particular communities and small dispersed populations, but it also allows studies that span many countries and large time spans. Restricted census microdata with full geographic information will allow analysis of the effects of local context on individual behavior at multiple scales, focusing on immediate neighbors, enumeration districts, and labor market areas.

Linked census microdata have shifted our perception of life-course change in the past. They have revealed that occupational mobility was far higher in the nineteenth century than it is today, migration was far more frequent, and the formation of intergenerational families was most common among the rich, rather than the poor (Ferrie, 2005; Ruggles, 2011). The next generation of linked microdata will be far more powerful, with 100 times the number of records, more reliable links, and coverage across entire lives and across multiple generations, allowing multilevel analysis of the demographic and economic context of mobility.

Abstract

In most countries around the world, the population census is a crucial tool of governance, providing vital information about a country's size, spatial distribution, and socio-demographic characteristics. This article identifies some of the defining characteristics of the population census and explores variations in census practices in an international context. The expansion in the conceptualization of the census, combined with the introduction of technological innovations in data capture, coding, and dissemination, has both complicated and enriched the possibilities for comparative census analysis in the regional and global contexts.

Introduction

In most countries around the world, the population census is a crucial tool of governance, providing vital information about a country's size, spatial distribution, and socio-demographic characteristics. Often the census is the only source of data from which it is possible to derive reliable estimates and social indicators for small areas and subpopulations. Although the systematic enumeration of a country's entire population is a quintessentially modern development, the counting of populations for military or taxation purposes dates back to ancient times. The United States census of 1790 is often credited as the first national population census, although it excluded Native Americans and counted Black individuals as only three-fifths of a person. The census spread throughout Western Europe and the 'New World' in the nineteenth century, and was ubiquitous by the middle of the twentieth century. In the current 2010 'census round' (2005–14), 227 out of a total of 233 countries had either undertaken or were planning to undertake some form of population census (United Nations, 2010).

With respect to its core features, the census has changed very little since the United Nations instigated its 'World Program on Population and Housing Censuses' 60 years ago (United Nations, 2010). Concepts such as universality, simultaneity, and periodicity (see below) are as important now as they were then. However, the ways in which countries compile census data has undergone significant change. The last decade, in particular, has seen a shift away from the traditional census approach, involving a total population enumeration at a single time point, to alternative census models which make greater use of register, administrative, and survey data (Coleman, 2013; Dugmore et al., 2011; United Nations, 2010; Valente, 2010). This expansion in the conceptualization of the census, combined with the introduction of technological innovations in data capture, coding, and dissemination, has both complicated and enriched the possibilities for comparative census analysis in regional and global contexts. These developments and their implications are discussed throughout this article.

Defining Features of National Censuses

Bodies Responsible for Population Censuses

Population and housing censuses are always undertaken by the national government, often under the auspices of a National Statistical Office (NSO) working within a set of statutory limitations relating to content and data confidentiality. Where data are used for the purpose of apportionment, separate legislation may also apply. Beyond political functions, census data are widely used to inform policy and planning at regional, national, and local levels, as well as for research, commercial, and other uses. Confidentiality is a core concept and influences how individuals' data are stored, coded, aggregated, and accessed. In some countries public access to individual census records is permitted after a certain period of time. In the US, access to individual census records is restricted to 72 years by law, while in Ireland it is 100 years.

Geographical Specificity

Each country's population census conforms to a set of core characteristics. The most distinguishing feature of a census is its geographic specificity, with the population to be counted clearly contained within a defined territorial boundary. Census geography is multilevel and ranges in granularity from national boundaries to small areas such as 'census blocks' (US), 'meshblocks' (New Zealand and Australia), and 'output areas' (United Kingdom). While some change to census geography over time is inevitable, this needs to be carefully planned. Sometimes data classification schemes have to be adjusted in order to preserve temporal comparability. There is no standard approach for the enumeration of nonsovereign territories and dependencies. In some cases, such as in Puerto Rico, the territory is included within the national census of the mainland; in other cases, such as the French overseas departments or territories (DOM-TOMs), a separate enumeration is conducted.

Household Data

Although the individual is the key unit of analysis for the population census, most countries that undertake a population census also enumerate dwellings so that household structure and characteristics can be analyzed alongside data on individuals. The dual population and housing census approach typically involves two separate census questionnaires: one is designed to elicit information on an individual's characteristics and circumstances; the other is concerned with the relationships of individuals within a housing unit and specific features of the dwelling. The distribution and planning of the housing census must also take into account individuals who do not live in regular housing, such as those who are homeless, refugees, or incarcerated. This is sometimes a controversial issue. In the US, for example, political power is based on the number of people residing in a legislative district. Consequently, decisions on the legislative districts, to which people are assigned, are highly politicized. For example, the incarcerated population in the US is concentrated in rural areas far from their home legislative districts. As a result, census counts are biased toward rural areas with prisons over urban minority areas, from where a disproportionate number of prisoners originate. In developing countries, group enumeration is sometimes used to enumerate nomadic groups, where only the number of persons for broad age-sex groups is recorded (Bryan and Heuser, 2004). Seasonal workers and individuals engaged in daily labor-related migration which takes them across national borders are another example of special populations for which different procedures might be used. Differences in how countries treat special populations can have an important effect on the estimated size of the world's population (Bailar, 2001). While the census aims to cover the entire population, some groups, such as military personnel serving overseas, are necessarily omitted. This is distinct from the exclusion of subpopulations on the basis of citizenship distinctions such as race, ethnicity, gender, and property ownership. The inclusion of absentee residents and overseas visitors depends on whether the basis of enumeration is *de jure* (place of usual residence) or *de facto* (location on census day). Making comparisons between countries that use different counting rules can be problematic, as is undertaking time-series analysis when there has been a shift from one method to another. In many countries census participation is compulsory by law, but responses to specific questions such as religious affiliation may be voluntary.

Simultaneity and Periodicity

Simultaneity enables the census to provide an entire population snapshot at a discrete point in time. For that reason the census is designated to take place on a specific date, even though the data collection process may stretch over weeks or even months. The census is usually undertaken at a time of the year when potential disruptions, such as the occurrence of extreme weather, are minimal. The duration of enumeration varies tremendously between countries and is influenced by a number of factors including resources, landmass, population size and distribution, and the availability of technology.

Periodicity refers to the frequency and regularity of the census cycle. The UN recommends that all countries conduct a census at least once in every 10 years, preferably closer to years ending in 0. Most countries, including the US, India, and England, conduct a decennial census, although some countries belonging to the former British Empire (e.g., Australia) undertake a census every 5 years. A spacing of exactly 5 or 10 years is desirable because it enables greater flexibility for cohort analysis and the presentation of results in standard demographic terms. Factors such as political unrest and natural disasters can lead to the delay or postponement of the census. The Christchurch earthquakes, for example, delayed the planned 2011 New Zealand census by 2 years. The delay or postponement of a single census can have longer-term implications if it leads to a permanent change in the frequency and regularity of the census cycle.

Census Content

Core Topics

In census-based analysis, household and individual level data are always clearly distinguished. Household data typically includes information on the structural characteristics of dwellings, occupancy information, and relationship characteristics of household members. Households are not the same as families although the terms are often used interchangeably by the public. As households may contain families or unrelated individuals living together, data on relationships within households is crucial for identifying the status of families. NSOs routinely employ socio-economic data on households and families to assess the relative well-being of their populations.

All censuses contain a large number of questions on key demographic variables for both individuals and households. Questions on age, sex, location of residence during census, number of occupants, and place or country of birth are nearly universal in their adoption across countries. Even small countries with limited resources contain some version of these questions. While the wording of core demographic questions varies across countries, there is generally a consensus on how to convert them into data. The classic demographic variable of age, for example, is always collected as an exact age, whereby respondents identify their age in exact years rather than a range of years. Likewise, sex is universally treated as a binary concept, representing either males or females. Other key variables like place or location of residence typically reflect exact locations based on recognized municipal designations and officially designated geographies. These core topics constitute a baseline set of variables around which countries build their census. In 2011 the European Union member states agreed to adopt a set of core topics to be included in each member state's census (Eurostat, 2011). These include individual level variables such as age, marital status, educational attainment, and occupation, in addition to household level variables such as housing arrangements, number of occupants, and type of ownership.

Core topics are particularly useful for demographic analysis of the population; consequently many NSO's allocate a sizable share of their time and resources to ensure the accuracy of these data (see Stukel, 2008 for a breakdown of expenditures for different countries). Age and sex are by far the most important of all information collected in a census. Nevertheless, despite

special attention given to ensure that errors of coverage are limited, errors do inevitably occur (Ewbank, 1981). Beyond age, sex, and location, the inclusion of other core topics such as marital status, residence, and place of birth are influenced by factors that include the census budget, the resources available to NSOs, and the availability of population register data.

Noncore Topics

The inclusion of noncore topics in the population census varies considerably across countries. NSOs with large budgets or those lacking population registers tend to include more questions than NSOs with limited resources or access to register-based alternatives. Ireland, for example, sent out a household survey in 2011 that was 24 pages long and included dozens of questions. Kenya's 2011 census questionnaire, on the other hand, was only two pages long, with far fewer questions. The extent to which a particular noncore topic (e.g., migration, literacy, or method of commuting) is deemed relevant can also influence its inclusion in the census. Countries with a high level of immigration, such as Canada and Australia, are more likely to include questions on migration than countries that receive less immigrants (e.g., China), although there are always exceptions.

Some noncore topics, including race, ethnicity, nationality, language, and religion, are not as universally adopted as the aforementioned topics. Indeed, some countries are hesitant about including these types of questions because of privacy issues or concerns about data being used for discriminatory purposes (Simon, 2007). While the United Nations has no formal recommendation regarding a universally accepted set of questions for race and ethnicity or related items (United Nations Statistical Division, 1998), the United Nations Committee on the Elimination of Racial Discrimination regularly advises states to collect information about these items (United Nations, 2012). From a conceptual perspective, identity-based questions are challenging because of the variable meanings that can be attributed to them, both across and within countries (Morning, 2008). Unlike demographic characteristics such as age and sex, socially ascribed identities such as ethnicity and language group are neither mutually exclusive nor consistent. The 2000 US Census, for example, allowed respondents to choose more than one race, which resulted in 2.4% of the population choosing more than one race. Native Hawaiian and Pacific Islanders reported a much higher mixed-race component at 54.4% (Jones et al., 2001). Quality analysis found that 60% of all respondents who chose more than one race in the 2000 census only reported a single race in follow-up surveys (Bentley et al., 2003).

The census is often used to evaluate the overall state of affairs in a country, making it both an important tool of scientific evidence and a flashpoint for political debate. Both core and noncore topics can be highly contested and the ultimate decision to include some and not others is as much political as it is practical. Likewise, socio-economic variables vary tremendously over time and place with respect to nomenclature, level of detail, and their conceptualization. Religious, ethnic, and national identities, for example, differ from country to country and can change dramatically even within individual countries over time. Similarly, as countries develop, the types of socio-economic variables also change. Unpaid work and time traveled to work are illustrative examples.

Recent Shifts from Traditional Censuses to Alternative Models

The substantial cost of undertaking a census, combined with the long spell between enumerations, has raised questions about the relevance and sustainability of the traditional census model. In countries where accelerated migration has led to rapid population turnover, the limited capacity of the census to capture these shifts has diminished its perceived usefulness. Growing objections to state-sponsored data collections, as well as the ballooning costs of censuses, have provided additional challenges (Coleman, 2013).

For many decades, only the Scandinavian countries used alternative methods to derive population data, but in the last decade the census has assumed a wider concept, particularly in Europe (UNECE, 2006). In the 2000 round, 18 of the 27 European Union countries (67%) responding to a United Nations Statistical Division (UNSD) survey had conducted traditional censuses (United Nations, 2010). By the 2010 round (until 2009), this had reduced to 11 countries. In most cases, the shift was to a combined approach utilizing a range of data sources including field enumeration, registers, and surveys. Of the four purely register-based countries, three were Scandinavian (Finland, Sweden, Denmark). The remaining country, Austria, shifted from a traditional census to a purely register-based model in 2011 (Lenk, 2008).

North America is interesting as the census approach in the US and Canada has undergone significant changes since 2000. In previous census rounds, a short census form was distributed to the entire population in both countries while a long form, asking detailed socio-demographic questions, was distributed to a random sample. For the most recent censuses (2010 and 2011, respectively) only short forms were used, with the long forms being replaced by sample surveys. In the case of Canada, the sample survey was entirely voluntary. At the time of writing, a number of countries were actively looking at alternative census models, among them the United Kingdom, Australia, and New Zealand (Coleman, 2013; Statistics New Zealand, 2012). France remains the only country in the world that uses a 'rolling census' model in which annual sample surveys are combined to cover 70% of the French population over a 5-year cycle (Valente, 2010).

The shift toward a more expansive concept of census has been aided by technological innovations enabling easier and more comprehensive linkage of administrative data. Although the infrastructural costs associated with establishing robust alternative models are significant, so are the long-term efficiencies and savings. In the US, for example, the expected average cost per head for the 2010 census was US$ 48.90. In many of the register-based or mixed census models of European countries such as Austria, Belgium, Denmark, and Norway, the cost per head was less than US$ 1.30 per head (UNECE Secretariat, 2010, Table 4; expected costs on a purchasing power parity basis). In Denmark the cost was a mere US$ 0.03 per head. Nevertheless, as has been demonstrated by countries that have recently transitioned from

a traditional census approach to an alternative model, there are significant challenges associated with census transformation, including population compliance and interagency collaboration. These challenges suggest that it will be many decades yet before the population census reaches its 'twilight' years (Coleman, 2013). The significant capital investment and high degree of public conformance required of registration systems suggests that register-based alternatives are likely to be restricted to developed countries with relatively well-established administrative data infrastructures.

Methodologies of Censuses

Methods of Enumeration

The decision to undertake a census raises a number of methodological issues that NSOs must address. The mode of administration is particularly important as it can have a direct impact on the accuracy of the data and the overall cost. The most common mode of enumeration is the face-to-face interview but changes in technology and concerns over budgets have made other types of administration more popular. A self-report sample of 124 countries reveals that 85% of these countries conducted face-to-face interviews in the 2010 round (United Nations, 2010). Of all the world's regions, Europe was the less likely to employ the face-to-face mode, followed by North America and Oceania. Other modes of enumeration include the paper-based self-enumeration mode, which is popular in North America and Oceania, and population registers, which are found primarily in Europe. A growing number of countries also appear to be utilizing web-based technologies. The 2011 Australian census recorded an online response rate of 33%, up from 9% in 2006 (Australian Bureau of Statistics, 2012). The 2011 rate for Australia was comparable with the target online response rate for the 2013 New Zealand census (35%), but somewhat higher than for the Czech Republic in 2011 (Coleman, 2013). The Internet is only used in combination with other modes of administration. However, given its significant cost-saving benefits, it is likely to be more widely adopted by NSOs in coming years.

Accuracy Assessment of Data

Each time a census is undertaken NSOs must also deal with coverage errors associated with miscounting the population, and content errors arising from the collection of incorrect information. Each country must adopt some method for dealing with these errors in a robust and efficient manner that corresponds to their resources and expertise. While there is no universally recognized agreement about the best methods for dealing with these errors, there have been some attempts to assist countries with data capture (United Nations, 2009a), editing procedures (United Nations, 2009b), coding practices (United Nations, 2009b), and post-enumeration surveys (PES) (United Nations, 2009c). Because the census is supposed to be an accurate count of a country's population, coverage errors assume high priority for NSOs. Net coverage (a report of the total difference between who was counted and who was not) and gross coverage (separate reporting for overcounts and undercounts) are the primary means of reporting coverage errors. Regardless of which way it is reported, the fundamental goal of evaluating census coverage errors is to determine who was counted more than once, and who was left out. In the US, for example, demographic analysis suggests that African Americans were undercounted by as much as 6.5% in 1970, and by about 2.5% in the 2010 census. By comparison, non-African Americans were only undercounted by about 2.2% in 1970, and were actually overcounted by .5% in 2010 (Mather et al., 2011).

Some countries provide detailed analyses of their coverage errors, while others do not. Developed countries typically engage in some form of post-enumeration analysis of content errors and coverage errors. Canada, for example, has been reporting on their coverage errors in their quinquennial census since 1961. Comparisons across countries show significant variation in coverage. In the 2000 census round, the net undercount was about 5.7% in the UK; 2.8% in Australia; 3.2% in Suriname, and 2.4% in Canada. Net coverage is dependent on a variety of factors and censuses do not always become more accurate. In Canada, for example, the net undercount estimate was about 2.4% in 1996 and 2.7% in 2006.

One of the primary methods of evaluating coverage and content errors is through a PES. In its most basic form, the PES replicates the census for a subset of the population and the results are compared to estimate coverage and content errors. A PES can be very complicated and resource intensive. However, at its core are the postenumeration sample (P sample) and the enumeration sample (E sample). The P sample contains a sample of the population independent of whether or not they show up in the census. The E sample is a sample based on census records (i.e., they were chosen based on their involvement in the census). The presence of the P sample allows NSOs to evaluate coverage errors and the inclusion of the E sample allows NSOs to evaluate content errors. Though not all countries use a PES to evaluate their censuses, a large number do use them on a regular basis. Demographic analysis is also commonly used, sometimes in conjunction with the PES, to evaluate the accuracy of a census. Demographic analysis is most often conducted by analyzing existing data from other sources, such as vital registrations or other registers that include basic demographic information. The US, for example, uses its Medicare enrollment database as one source of data in its demographic analysis of the total population (U.S. Census, 2010). Suriname, however, uses a subset of its census and compares it to expected distributions of the population, based on various characteristics. For example, it compares the age distribution of its census sample to the UN age-sex accuracy index. Other strategies for conducting demographic analysis include errors of coverage analysis, comparisons of age and sex distributions across censuses, and a variety of other demographic comparisons to known distributions of the population.

There are other means of assessing the accuracy and validity of censuses, such as the use of record checks to estimate coverage. Canada has used a sophisticated version of the record check, known as the Reverse Record Check (RRC), to evaluate its coverage since 1961. The RRC is a procedure that takes a random sample of the population using other sources of data and then address matches it to census data to

compare the accuracy of the census. The RRC is a very effective way of estimating net coverage but is reliant on accurate sources of alternative data that can be linked to census data.

Finally, analysis of census evaluation procedures across countries reveals that not all countries use them for the same reasons, or as extensively (United Nations, 2010). In a sample of 124 countries which reported on their usage of PES, 78% reported using a PES, either alone or in conjunction with demographic methods; 16% reported only using demographic methods, and 6% reported that they only used other methods to evaluate the accuracy of their census. While most countries (97%) reported using the PES to evaluate coverage errors, a smaller number of countries (74%) used them for evaluating content errors.

Data Processing and Dissemination

Data Processing

The processing of census information includes all the tasks associated with taking the original information collected in the field and making it available to end users. Historically, this process includes data editing, coding, tabulation, verification, review, and the preparation and presentation of the census results (Shryock et al., 1971). Data capture techniques have changed considerably from the days when all data was captured through manual entries on paper forms. Optical mark reading (OMR), where scanners automatically detect tick boxes or other information; intelligent character recognition software that automatically recognizes handwriting; personal digital assistants (PDA) handheld devices for recording information; and telephone and internet technologies are all being used to assist in data capture (United Nations, 2009a). While some developing countries, like Mauritius in 2000, continue to use manual entry to capture data, others have adopted various data capture strategies that reduce costs and increase efficiency. In Ethiopia for example, OMR has effectively cut the time taken to process census data from 18 months in the 1994 census to around 4.5 months in the 2007 census (United Nations, 2009a).

Once captured, census data are typically edited (correction of errors) and coded (assignment of values) before final verification and presentation of the data. In the past, much of the editing and coding was performed by hand in the field office or in conjunction with machine-readable cards that changed or added missing information, based on a set of predetermined rules (Shryock et al., 1971). Much of this work has been replaced by computer-assisted methods for coding and editing data. Few countries solely use manual techniques for editing and those that do, tend to be concentrated in Latin America and the Caribbean (United Nations, 2010). Most use some combination of automated and manual editing techniques (United Nations, 2010). Many countries outsource various tasks during the processing and dissemination stages of the census. Confidentiality becomes an important issue with the outsourcing of data processing and many countries have begun to establish guidelines and policies for dealing with the confidentiality issues involved in censuses.

Dissemination of Data

The processing of data plays a critical role in connecting end users to the census. Generally, the dissemination of data is in the form of a print publication or some form of electronic media. The electronic media can take several forms, including devices such as DVD/CD, websites, online sources, and/or Geographic Information Services (GIS). A variety of software sources and electronic data tools also exist to provide users with one on one interaction with census data. Instead of simply providing printed publications, electronic interfaces with census data have emerged around the world. 'American Factfinder' in the US and 'NZ. Stat' in New Zealand, for example, give users an opportunity to interact with the data in ways that were not possible even as recently as the 1990s.

Censuses in Comparative Contexts

As the flow of people, goods, and ideas across national borders has rapidly expanded, governments and international organizations have become more aware of the potential benefits of using census data for comparative purposes across countries and regions. The UNSD has been a leading advocate for the collection and dissemination of population and housing census data in accordance with the UN's recommended principles (United Nations, 2008). Data harmonization is an important issue in the European Union where comparable data is crucial to regional policymaking and governance. In the 2010 census round, the European Parliament passed a number of regulations aimed at improving comparability of census data across member states. According to Eurostat, the agency which coordinates statistical activities across the EU, the legal and technical framework set up for the 2011 census far exceeds previous attempts to integrate data regionally (Eurostat, 2011: p. 10). Because of diverse approaches to census collection in Europe, the framework has focused on achieving harmonization of census output rather than input. One of the preconditions for comparability of census output is that every member state follows the same definitions and technical specifications, and publishes the same breakdowns. Each member state also has to provide cross-classified census data in the form of hypercubes to Eurostat, which allows for regional comparisons across a range of standard socio-demographic variables (Annex I, Regulation (EU) No 519/2010).

Another relatively recent innovation in the dissemination of census data is the systematic sharing of integrated individual-level micro data. IPUMS-International (Integrated Public Use Microdata Series-International) has the world's largest archive of publicly available census samples, holding more than 200 census samples from 68 countries, and dating back to the 1960 census round. The anonymous datasets are freely available to qualified researchers through a web dissemination system. Output harmonization is a key feature of the project, with micro data coded and documented consistently across countries and over time, to enable comparisons. Notwithstanding the significant advancements that initiatives like the EU framework and IPUMS-International have made with respect to facilitating census-based comparative research, some variables,

such as migration status, ethnicity, and race, continue to pose major challenges (Bell and Muhidin, 2009).

Future Prospects for Censuses

The national census has a long and rich history and continues to be widely viewed as an integral tool for national and regional governance and planning. In the twenty-first century, however, political and fiscal concerns, along with the demand for more timely data, have stimulated NSOs to explore census alternatives. There is little doubt that ongoing technological advances in data capture, management, and integration systems will further expand the possibilities open to governments, albeit within the constraints of legal requirements and confidentiality concerns (Coleman, 2013). Furthermore, as new methods in geospatial, post-enumeration, and statistical sampling techniques become more widely incorporated into national censuses, the need for new technologies and the demand for NSO staff skilled in these practices will also increase, both to process and interpret the results of these censuses (Coleman, 2013).

Growing pressures to harmonize data and standardize collection practices, along with concerns about the costs of administering a census and the need for more frequent data, means that countries will continue to adopt new strategies for counting their populations. However, the extent to which a country engages with new technologies or incorporates the most efficient and productive enumeration practices into the census, will continue to be heavily influenced by socio-political factors. The US is as an illustrative example of how politics may outweigh resources in the quest to develop new and better ways to enumerate the population. Despite having one of the most advanced NSOs in the world, with significant economic resources (the US spent roughly US$ 13 billion on the 2010 census alone) and access to advanced technologies, the adoption of new technologies has occurred much later in the US than in other industrialized, census-taking countries. The apparent reluctance to use the internet to supplement paper forms and to incorporate statistical adjustments into its census (which has been outlawed), means censuses in the US are in some ways anachronistic. Its geographic neighbor to the north, Canada, recently conducted over 50% of its census online and is a strong advocate of statistical adjustments for a variety of purposes. In 2011, Brazil completed its first entirely digital census through the use of PDAs. In the end, the politics of counting the population (Skerry, 2000; Anderson and Fienberg, 2001; Prewitt, 2003) may well trump the desire to count accurately.

Abstract

The population census is the official counting of a population in the territory of a country and the collection of information on selected demographic and socioeconomic characteristics of the population. Almost all countries conduct a population census at least once every 10 years, often together with a housing census, which is the official counting of the housing stock and collection of housing characteristics. The traditional approach to the population census consists in the registration of all individuals and their details using paper questionnaires during a field operation that normally lasts a few days or weeks. Some countries conduct censuses using data from population registers and other administrative sources, without collecting data in the field. Recently, various alternative census approaches have been developed, making use of register data combined with field data collection and other sources, as well as partial annual field data collection and other sampling methodologies.

Definition/Overview

The population census is the operation that produces the official counting of the population within the territory of a country and its smallest geographical subterritories, as well as the registration of selected demographic and socioeconomic characteristics of the population. Almost all countries conduct a population census at least once every 10 years, frequently together with a housing census, which is the official counting of the housing stock and collection of selected housing characteristics.

The population census plays a key role in the administration of a country as its results are generally used for many important purposes, e.g., allocating funds to regional governments and municipalities or defining electoral districts. Census results also influence key policy decisions at the national and local level with regard to economic development, infrastructures, provision of education, health, and other services to the population.

Population censuses are also important for national statistical systems. In fact, the census not only provides the benchmark for the population count at national and local levels, but also represents the best or sometimes the only source of data on small population groups. Moreover, censuses allow the creation of a solid framework that can be used to draw samples from all other surveys conducted in the country. The role of the population census is even more important in countries where other vital statistics are not complete or accurate: in these countries, the census is the only statistical source providing correct and detailed estimates of the population size and structure.

The Traditional Census

The methodology used to conduct a census has been basically the same for centuries, starting in the ancient world. Evidence suggests that censuses were carried out already around 4000 BC by the Babilonians. At that time censuses were taken every 6–7 years to take record – on clay tiles – of the number of people and livestock, and to know how much food was needed for the population. In Egypt census were taken from around 2500 BC and the results were used – among other purposes – to plan how to share out the land after the annual flooding of the Nile and to calculate the labor force available to build the pyramids (ONS United Kingdom, 2013; CSO Ireland, 2013). Censuses were conducted regularly also in China and in ancient Rome (the word census comes from the Latin word 'censere' which means 'to estimate'), by recording all individuals and their details through the completion of population lists. More recently, census forms replaced the lists, but the information is still collected in the field across the whole country in a relatively short period of time, normally within a few weeks.

Traditional censuses in modern times used two main alternative methods of enumeration. In the first method, census enumerators (temporary staff recruited for the census field data collection) are responsible for collecting the information from the households with the help of an interview and the filling out of census forms. This approach is usually adopted in countries where a relatively high proportion of the population has minimal standards of education or is illiterate. This method is particularly expensive because enumerators have to conduct interviews in addition to delivering and collecting the forms.

In the second method, called 'self-enumeration,' forms are filled in by the members of the household. The enumerators deliver the forms to the households and collect them some days later. In some countries where this method is adopted, the postal system is used instead of enumerators for the delivery and/or the collection of the forms. More recently, some countries have offered the option to fill in the census questionnaires on the Internet, as an alternative to filling the paper forms.

Some countries use two types of questionnaires to reduce the amount of information to be processed. They supply only a sample of the population with an extensive long form, while a short form is used for the rest of the population. This method has the advantage of providing extensive details about the population, yet reducing the amount of time and labor to process the collected information. This also limits the complexity and costs of the census operations. However, since the information collected with long forms only represents a sample of the population, census results on detailed

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41006-8

characteristics (covered in the long form) are not available for small areas or small population groups. This approach has been used in the United States and Canada since the 1970s. For the 2010 US census, the long form was replaced by a large household sample survey (the American Community Survey or ACS) that is conducted every year and provides detailed demographic, social, and economic data about households. As a result, the US census model for the 2010 census is based on a decennial traditional enumeration – conducted in 2010 using only a short form – with yearly updates of the population characteristics on a sample basis provided by the ACS.

Although the concept of the traditional census is relatively simple, its implementation is a huge and very complex operation that requires significant financial resources, the participation of various administrations at central and local levels, as well as the recruitment and training of a large temporary work force hired as census field staff (enumerators, supervisors, etc.).

From the point of view of the census management, there are also a number of problems and issues when it comes to the traditional approach. First of all, recruiting and training a very large temporary work force to collect data implies huge costs. But there are also other activities required for a traditional census that are very expensive, like printing, distributing, collecting a huge number of census forms, entering the data (manually or using scanners), and processing them. Moreover, in a traditional census, the costs are concentrated around the year when data are collected and are much lower in the other years of the census cycle. This cost distribution over time can create management and budgeting problems.

From the point of view of the organization of the fieldwork operation, a census conducted with the traditional approach normally requires the cooperation of various administrations at the national and local level (including government departments, cartographic agencies, postal administration, municipalities), which may pose problems in some countries, especially if the budget does not fully cover the census expenses, or if the respective tasks and responsibilities of the various administrations involved are not clearly specified.

An emerging problem reported by countries using the traditional census model is the increasing difficulty to enumerate certain population groups, particularly those characterized by high mobility and multiple residences (including young professionals, students, workers, retired people, or other categories that commute regularly between two or more places). In general, it can be difficult to find these persons at home in order to deliver or collect the census forms. Moreover, identifying the place of usual residence for these people is often complicated.

Several countries have reported an increasing reluctance of the population (in particular among specific subgroups) to participate in the census. This can be due to various reasons, including reluctance to open the door for security reasons, in particular by old people or in areas with security problems; distrust toward statistical institutes or the public authorities in general; fear that the information collected could be used for purposes other than statistical uses; and reluctance to provide information that is already available in registers or other administrative sources.

Finally, there are also some problems with the outputs produced by traditional censuses. Publishing census results often takes a long time because of the large amount of information that is being processed. The frequency of the results of a traditional census is often not considered to be acceptable. In fact, the traditional census is normally conducted every 10 years due to its costs and complexity. However, there is a certain necessity from various users to obtain more frequently updated data than every 10 years.

The Register-Based Census

The most common alternative to the traditional census approach is the so-called register-based census. With this method, traditional field enumeration is replaced by the use of administrative data coming from various registers and administrative sources (population registers, building registers, social security registers, business registers, student/education registers, etc.) through a matching process. The matching is normally done making use of a personal identification number (unique for each individual) that should be included in the various registers. By this method, it is possible to match demographic, education, economic, and social data on individuals existing in a large number of registers (UNECE, 2007).

This approach, developed by several Nordic countries in the 1970s and adopted for the first time in Denmark in 1981, permits the production of census data at a limited cost and with relatively limited work, once a good quality system of statistical registers has been set up. This approach has the advantage of placing no burden on individuals and updated data are potentially available every year. Moreover, there is no cyclic distribution in the costs and census staff, as they are distributed relatively evenly across time.

It should be noted that setting up and maintaining a statistical system based on registers requires significant initial investments and a very long development time. Moreover, this approach requires good cooperation between the authorities responsible for the registers and national statistical institutes, because data have to be transmitted from the former to the latter following specific formats and deadlines. Legislation that allows using administrative data for statistical purposes and matching records across registers is also required, as well as acceptance by the public of such a system.

Another disadvantage of this approach is that the details to be collected are limited to those available in registers, and the quality of the data depends on the coverage and quality of the registers themselves. However, statistical agencies can combine data from different registers to assess and increase quality and derive new variables. Another way to provide data on variables that may not be available from registers is to make use of results from existing household sample surveys. An example is the so-called Virtual census conducted in the Netherlands in 2001 and 2011, where register data were integrated with results from the labor force survey (LFS) on some of the economic characteristics that were not adequately covered in the registers. This approach allows producing census data without field data collection, but the detail of the information derived from sample surveys is clearly limited.

The Combined Census, Based on Data from Registers and Field Data Collection

Many countries have registers with population and other data that could potentially be used for a census, but the coverage and quality of the data are not sufficient for producing reliable census data. Sometimes key census variables (for instance, on occupation, educational attainment, or the composition of households) are not available. Some of these countries have used data from registers in combination with data from exhaustive or partial (sample) field data collection in order to produce census results.

Data from the registers can be combined with data from sample surveys conducted ad-hoc to fill in the gaps or confirm already existing data. Hence, the purpose of additional surveys is usually to evaluate the accuracy of population registers and/or to collect information on topics that are not covered in registers, or for which the coverage and quality of registers is not sufficient. The method has the advantage that costs and burden on individuals for providing information are limited, because surveys are just submitted to a sample of the population. Moreover, by comparing the data of the sample surveys with those from the registers in the same areas it is possible to assess the accuracy of the registers, and possibly make adjustments to the population counts derived from the register. This method was adopted in 2008 by Israel for the first time and in 2011 by various other countries in Europe.

Another approach to combined censuses is based on using data from registers in combination with full enumerations in the field. The field enumeration provides information about the coverage and accuracy of the data available in the registers, and allows collecting information on variables not available in registers. This approach is more expensive than the previous one because the whole population is counted, but it is in general less expensive than a traditional census, because of the efficient use of data available in registers. Compared to a register-based census, this method is clearly much more expensive and poses response burden on the public, but on the other hand it provides improved precision of the results and may help to increase the coverage and quality of registers. For this reason, this method is sometimes used to transition from a traditional to a fully register-based census.

Often, when a combined census approach is used – with either samples or full field data collection – the respondents have the opportunity to fill in web-based census questionnaires. The Internet option is generally considered to be more beneficial, especially in terms of improving/maintaining the census participation among population groups that would be difficult to enumerate in a traditional way; responding to social/public expectations; improving data quality; and reducing costs if a significant proportion of the respondents fill the questionnaires on the Internet.

The Rolling Census

With this method, the census is conducted by a cumulative and continuous (or 'rolling') field data collection over long periods of time, rather than during a relatively short time period as in the traditional census. This is the only alternative census methodology that does not require using data from population registers or other administrative data. This method was developed in theory in the 1970s, and first implemented in France starting in 2004 (see later). Under this method, data are collected in the field every year in the various municipalities on a rolling basis. In France, for instance, a 5-year cycle is used. The census results are based on rolling averages calculated over the 5-year cycle and are updated yearly. This method provides for improved frequency of data and spreads out across time the financial and human burden associated with censuses. However, this method is complex and hard to implement. Complications may arise from movements of persons across municipalities over the various years. These movements could potentially lead to double counting or missing certain individuals, although specific mechanisms have been put in place to deal with these cases.

Global and Regional Trends about Census Methodology

As mentioned earlier, historically and until the 1970s, population censuses were conducted in all countries across the world exclusively using the traditional approach. During the 1970s, some countries in Northern Europe started developing the register-based census. The first register-based census was carried out for the first time in 1981 in Denmark, followed by other Nordic countries in the 1990s. Outside Europe, Singapore carried out in 1990 a combined census, based on data from registers and field data collection. However, basically all other countries in the world were still using the traditional census approach until the 1990s.

For the 2000 census round (covering the period from 1995 to 2004, according to the United Nations), the number of countries using alternative census methods increased significantly in Europe: three countries conducted a register-based census (without field data collection) and five countries conducted a combined census. In total, 8 European countries out of 38 that conducted a census (21%) adopted an alternative method. Outside Europe, in the 2000 round only few countries including Bahrain and Singapore conducted a combined census, and the traditional approach remained the dominant method.

In the 2010 census round (covering the period from 2005 to 2014), the trend toward the adoption of alternative census methods became even stronger in Europe. The number of European countries conducting register-based censuses passed from three in the 2000 round to nine in the 2010 round, and those conducting a combined census from five to eight. If we also include France with its new rolling census, then the total number of countries that adopted an alternative census method more than doubled from 8 in the 2000 round (21%) to 18 in the 2010 round (42%). Outside Europe, Israel and Turkey joined Bahrain and Singapore among the few countries conducting a combined census in the 2010 round, but the traditional approach continues to be the method adopted by almost all countries, in some cases with Internet response or other innovations.

Selected National Census Methodological Practices

A selection of census methods adopted by countries in the 2010 census round, including traditional, combined, register-based, and rolling censuses, is presented. Several of the examples presented refer to European countries since the proportion of countries adopting alternative census methods is particularly high in this continent. In this regard, it should be noted that the European Union member states were free to decide the methodology, sources, and technology to be used for their census. In fact, the EU census legislation was concerned with the census dates (the reference date had to be in 2011 for all EU countries) and the harmonization of the census output rather than the input, including methodology and sources (EU, 2011).

United States: Traditional Census with Yearly Updates (2010)

Since the first census taken in 1790, the United States has been conducting censuses regularly, and often introduced important innovations. In 1890, punch cards and machine tabulation of responses were introduced. In 1940, sampling was introduced: long forms were used to collected detailed information from about 15% of the population, while the rest of the population filled a short form with only limited information. In 1950, tabulation was made using a dedicated computer. In 1970, the census became mainly a mail enumeration: since then the large majority of the population receive and return the forms by mail, and enumerators are used only for nonresponse follow-up (US Census Bureau, 2013a).

For the 2010 census, the enumeration was conducted using only a short form asking 10 questions (name, gender, age, race, ethnicity, relationship, and whether the home was owned or rented). Approximately 74% of the households returned their census forms by mail; the remaining households were counted by census workers throughout the United States. Detailed information on education, housing, jobs, etc. that in previous censuses was collected with long-form questionnaires, in 2010 was collected by the ACS, a large annual household survey launched in 2005, covering approximately 3 million addresses annually. Participation in the ACS, as in the 2010 Census, is mandatory by law (US Census Bureau, 2013b).

Canada: Traditional Census with Internet as Primary Response Channel (2011)

In Canada the first modern census was conducted in 1871, and then censuses were carried out regularly every 10 years. In 1941, sampling was used for the first time: one-tenth of the households were asked additional questions on housing. This use of sampling was considered effective, yielding high-quality data while reducing costs and response burden. In 1951 and in subsequent censuses, the sample was expanded to one household in five in order to obtain greater geographic detail. Starting in 1956, mid-decade censuses were conducted regularly. In 1971, self-enumeration (i.e., respondents complete their own questionnaire) replaced interview as the main enumeration method, and sampling was extended to include population data, using 'short form' and 'long form' (see earlier text). In the 2006 census, forms were delivered by Canada Post to about 70% of households, and for the first time households could complete their questionnaire online (with a 18.5% take up rate) (Statistics Canada, 2013).

For the 2011 census, major innovations were introduced. The questions normally asked on the census long form were asked in the National Household Survey. Questionnaires for this voluntary sample survey were distributed approximately 4 weeks after the census. All households were asked to complete 10 questions on basic topics (the 'short form'), and Internet response was promoted as primary enumeration method, with the objective to ensure better quality data and reduce costs. The majority of households received by post a letter replacing the traditional paper questionnaire, to encourage respondents to complete the questionnaire online. The paper questionnaire was still available on request. The Internet response target was set to 40%, but the final take up rate was even higher: 54% of households responded by Internet (Statistics Canada, 2012).

Israel: Combined Census (2008)

Israel conducted six censuses since its establishment. The first one was carried out in November 1948 and was used as the base for the Central Population Register (CPR). The four censuses that followed were conducted as classic censuses in which the whole country's area was canvassed, all possible dwelling facilities were enumerated, and a demographic short questionnaire was completed by the interviewer for 100% of the residents. A short socioeconomic questionnaire was completed for one-fifth of the households. All of the five first censuses were conducted with face-to-face interviews, using paper questionnaires (CBS Israel, 2012).

In 2008, Israel carried out an innovative combined census (called 'Integrated census'), consisting in a register-based census complemented by two sample surveys aimed to evaluate the quality of the register and to supply parameters for calculating corrections to the data from the CPR. The approach was intended to combine the advantages of both traditional and register-based censuses. The advantages of this approach consisted in reducing the burden on respondents (as only part of the population had to answer the questionnaire) and improving the quality of information available in registers (CBS Israel, 2013).

Turkey: Combined Census (2011)

The first census of Turkey was carried out in 1927. The following population censuses were carried out regularly every 5 years between 1935 and 1990, and then in 2000. The traditional method was used, with the particularity that data were collected in 1 day by application of the curfew. The enumerators visited all the households in the country and filled in the questionnaires by face-to-face interview. The population was enumerated on the basis of the place where each person was physically present on census day (*de facto* population).

The 2011 census was based on a combined method, using data from population registers and conducting a register-based large-scale sample survey. The backbone of the census was the Address-Based Population Registration System, established in 2007 in order to record and update information on the

population of localities, and to register population movements. The sample survey provided information that could not be derived from registers. The survey covered 13.5% of the total households, was conducted with interviews, using paper questionnaires and netbooks (Computer Assisted Personal Interview, or CAPI), and the duration of the data collection was 2 months (Ural, 2012).

Estonia: Combined Census with Internet as Primary Response Channel (2011)

The first population census of the Republic of Estonia took place in 1922, with a very exhaustive questionnaire. The data collection lasted 2 days but data processing took one and a half years, even though two special tabulating machines, designed specifically for population censuses, were used. Other censuses were carried out in 1934, 1941 (during the German occupation), 1959, 1970, 1979, and 1989 (as part of the Soviet Union censuses, with data processed centrally in Moscow). After the restoration of independence, the first census was carried out in 2000, with a traditional method using a household and dwelling questionnaire and a personal questionnaire. Processing of the results was a major challenge for Statistics Estonia, as there was no prior experience of processing census datasets in the country (Statistics Estonia, 2013).

The population and housing census of 2011 was based on a combined methodology and the intensive adoption of modern technologies. The method consisted of self-enumeration via Internet (e-enumeration) and traditional face-by-face interview using laptops. Paper questionnaires were considered only as a backup for emergency situations. Selected variables were taken from registers (when coverage and accuracy were considered sufficient) and used for prefilling the questionnaires, to be then verified by the respondents, and corrected if necessary. In the period before the census, an intensive publicity campaign was launched, motivating the population to use the Internet response option. The response of the population was exceptional, and the participation in the Internet census exceeded the projections, reaching almost 67%. The nonresponse follow-up was carried out by enumerators using laptops instead of paper questionnaires. The goal of the new solutions adopted was to ensure a bigger coverage for the census, better quality, and faster publication of the results (Beltadze, 2013).

Poland: Combined Paperless Census with Extensive Use of Technology (2011)

The first census in Poland was carried out in 1789, and the results were used to collect a tax covering the costs of maintaining a permanent army. Other censuses were carried out in the following decades more or less at regular intervals. In 1918, the Central Statistical Office was established, and censuses were then carried out at regular intervals (except for the period of World War II) between 1921 and 2002, with a traditional method. From the 1970 census, data have been captured, processed, and stored electronically (Pappelbon, 2011).

For the 2011 census, a new very innovative model was adopted, based on the combined use of data from about 30 administrative registers and data obtained from respondents (via Internet or with direct or telephone interviews), exclusively with the use of electronic questionnaires prefilled with data from registers. As a result, paper questionnaires were eliminated altogether, and replaced by IT solutions. GIS technology was used for the census preparatory work and for on-going census process monitoring. The new census model, that was considered very successful, was adopted to minimize census costs and burden on respondents (considering increasing nonresponse in statistical surveys) and to take advantage of the intensive development of IT systems of public administration, based on advanced technologies (Dygaszewicz, 2013).

Netherlands: Register-Based Census Using also Data from Existing Surveys (2001 and 2011)

In the Netherlands, the first census was held in 1795 for the purpose of establishing voting constituencies. After the establishment of Statistics Netherlands in 1899, six traditional censuses were carried out between 1909 and 1971. At the time of the 1971 census, the willingness of the population to participate had fallen sharply due to privacy concerns, and the decision was taken not to conduct traditional censuses anymore. Starting in 1981, the censuses were based on registers and surveys available at Statistics Netherlands. The data that have been compiled in 1981 and 1991 were of limited character, while in 2001 Statistics Netherlands developed for the first time the so-called virtual census, that was then repeated in 2011.

The virtual census uses a combination of available registers and surveys. The backbone of the census is the CPR, which is the combination of all municipal population registers. Other registers and databases are also used, including the Social Statistical Database with data on employees and self-employed. Different variables that are not available from registers, such as occupation and level of education, are obtained from the LFS or other surveys. To ensure numerical consistency in the set of census tables between data from registers and sample surveys, a new estimation method called 'repeated weighting' was developed, based on the repeated application of a regression method. According to Statistics Netherlands, the virtual census is cheaper (costing only about 1% of the traditional census in the Netherlands, but excluding the costs of the registers), comparable with earlier Dutch censuses, and more socially acceptable. However, for the variables derived from sample surveys the level of detail is clearly lower compared to a traditional census due to the use of sampling (Schulte Nordholt et al., 2004).

Austria: Direct Transition from Traditional to Register-Based Census (2011)

In Austria, censuses were carried out already since the eighteenth century, mainly to serve military and fiscal purposes. Modern censuses, aimed at serving the needs of the administration of the state, were carried out from 1869 at regular intervals. After World War II, censuses were conducted from 1951 every 10 years, covering population and housing. In the 1990s census taking became increasingly controversial, due to high costs, low frequency, and increasing reluctance in filling in forms. As a result, it was decided that the 2001 census would be the last traditional census.

In 2011, Austria carried out its first register-based census (after a test census in 2006), using information taken directly from existing administrative registers. The CPR represents the backbone of the register-based census. Other registers used include the Housing Register of Buildings and Dwellings, the Business Register of Enterprises and their Local Units, and the Register of Educational Attainment – all of which are maintained by Statistics Austria – as well as the Central Social Security Register, the Unemployment Register, and the Tax Register. The new register-based census of Austria, compared to the traditional census, is expected to be less expensive and to provide data sooner and with higher frequency (tentatively every 5 years) (Statistics Austria, 2013).

France: Rolling Census (Implemented Since 2004)

In France, the first census of modern times was carried out in 1801, under Napoleon Bonaparte. Subsequent censuses took place every 5 years until World War II, and then at irregular intervals (every 6–9 years) between 1946 and 1999, using the traditional method. Since 2004, the new rolling census was introduced for the first time, with the objectives to meet the expectations of census users (particularly in terms of frequent updates of the results), and facilitate census management in terms of constant budget over time.

As mentioned earlier, the rolling census is based on a cumulative and continuous (or 'rolling') field data collection over long periods of time, rather than during a relatively short time period as in the traditional census. In France, a 5-year cycle is used, with two different strategies to collect data of small municipalities (population under 10 000) and large municipalities. Small municipalities are divided into five groups, and a full enumeration is conducted each year in one of the groups. In large municipalities, a sample survey covering 8% of dwellings is conducted each year. At the end of the 5-year cycle, the population of small municipalities (which in France amounts up to about half of the total population) is fully enumerated, in addition to about 40% of the population of large municipalities. In total, about 70% of the country's population is enumerated. This is considered to be sufficient to guarantee robust information at the municipal level.

The census results are based on rolling averages calculated over the 5-year cycle and are updated yearly. Since the data collection for the French rolling census started in 2004, the first results for the population at the national level were based on data collected in the 5-year period 2004–08, with 2006 used as reference year being the central year of the period.

Abstract

A census is a complete count of a population, generally a nation, conducted by government, as of a fixed date. The periodic, national population census became a common function of Western governments around 1800 and is now routine throughout the world. Government agencies contact households to provide information for each member on a small number of questions such as age, sex, relationship to head. The agency tabulates responses and publishes the results. Data serve a variety of functions, including political apportionment, program planning, funds allocation, marketing and forecasting analyses. Censuses are expensive, logistically and technologically complex public activities, and serve to focus public attention on demographic patterns and change.

A census is a complete count of a population of a geographic area, generally a nation or country, conducted by the government. It is the most common method used for population measurement. Other methods include population registers and sample surveys. While governments have conducted censuses since ancient times, the regular periodic national population census only became a common function of Western governments in the late eighteenth and nineteenth centuries. The practice is now routine throughout the world. The basic historical continuity in census practice over time is straightforward. Government statistical agencies conduct censuses by contacting the household reference person in every residential household in person, or by postal mail or electronic means. The respondent provides information for each household member on a small number of questions such as age, sex, relationship to head, and other demographic markers. Individual-level data are generally considered confidential. The government statistical agency tabulates the responses and publishes the results. Data are used for a wide variety of public functions, including political apportionment, program planning, and funds allocation. The private sector uses census data for planning and marketing. Social science researchers and the media use the data to monitor demographic trends and illustrate social change. Within this broad outline, improvements in method and use result in more accurate, detailed, and timely data over time, and in shifting political and scientific demands on the particular census.

Definition/Overview

A census is a count of the population of a country as of a fixed date. National governments conduct censuses to determine how many people live in different areas of the country, whether the population is growing, stable, or declining in the country as a whole or in particular parts of the country. They also determine what the characteristics of the population are in terms of age, sex, ethnic background, marital status, or income. The traditional method is for governments to collect the information by sending a questionnaire in the mail or an interviewer to every household or residential address in the country. The questionnaire asks the head of the household, or a responsible adult in the household (the respondent), to list all the people who live at the address as of a particular date, and answer a series of questions about each of them. The respondent or the interviewer is then responsible for sending the answers back to the government agency, which in turn adds up the results, or tabulates or aggregates the answers from the country overall and for political subdivisions such as states or provinces, cities, counties, or other civil divisions. The agency usually reports the results to the public a few months or years after the census; the results are considered 'news' and are reported in the media. Since censuses aim to count the entire population of a country, they are very expensive and elaborate administrative operations, and are conducted relatively infrequently, generally at 5 to 10-year intervals.

Between censuses, governments estimate the size and characteristics of the population, either by extrapolating the trends in the census into the future, estimating the population from other data systems such as tax or drivers license records, or by conducting periodic sample surveys to collect information about the population. Representative probability samples collect information from a small portion of the population, and thus can be conducted frequently, even monthly. In the USA, the Current Population Survey of around 60 000 households is conducted monthly. National governments also conduct other types of censuses, particularly of economic activity, such as an agriculture, manufacturing, or business census. Such censuses collect information on the number and characteristics of farms, businesses, or manufacturing firms. In the nineteenth century, such censuses were conducted at the same time as the population census. Today, the economic censuses are generally conducted on a different schedule from the population census.

History

Censuses have been taken since ancient times by emperors and kings trying to assess the strength of their realms. These early censuses were conducted sporadically, and generally served to measure the tax or military capacity of a particular area. They tended to count adult men, men liable for military service, or people liable to tithe (pay taxes). For census taking of an entire

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41007-X

population to become feasible, a uniform unit of analysis was required. Hence census taking in the West had to await the emergence of the concept of commensurate households, generally seen as a development of the Medieval European West (Herlihy, 1985). The household or family served as the unit or analysis or the locus for counting the members within it.

Generally speaking the modern periodic census of all persons is an invention of the early modern period in the European West and, particularly from a New World perspective, was associated with efforts by the home country to determine the success of the overseas colonies. Thus the British Crown and the British Board of Trade ordered repeated counts of the colonial American population in the seventeenth and eighteenth centuries, starting in the 1620s in Virginia (Wells, 1975; Cassedy, 1969). In Canada, French efforts to count the population began in 1665–1666 when Jean Talon came to the New World on behalf of Louis XIV and took a census of what became Quebec. Censuses were continued at irregular intervals after Canada became a British colony in 1763 (Worton, 1997). By the early nineteenth century, census taking began to be a regular feature of government in Western Europe and North America (Alterman, 1969; Nissel, 1987; Glass, 1973; Desrosieres, 1993; Patriarca, 1996). The International Statistical Congress (established 1853) and the International Statistical Institute (established 1885) proposed and promoted the uniform regular censuses for all national states. In the twentieth century, census taking spread throughout the world. Currently, the 2010 World Population and Housing Census Programme of the United Nations Statistical Office provides guidance and support for census taking worldwide.

Functions and Techniques

Censuses serve a variety of purposes in different countries. At a minimum a census provides a measure of the size of the population of a country, which can be compared with the population in the past, the population of other countries, and to make estimates of the likely population in the future. Governments use census information in almost all aspects of public policy, from determining how many children an educational system must serve, to determining where to put new roads. Censuses are also used to provide the denominators of other measures, e.g., measures of per capita income for a state or local area, or for such measures as crime rates or birth or death rates. Private businesses use census data for marketing analyses to determine where to locate new businesses, or to decide where to advertise particular products.

Other government agencies and private researchers use the census to provide the 'sampling frame' for other survey research. This is the address list that researchers use to determine where to conduct a sample or poll. In the USA, the US Census Bureau conducts the census during the 10 year of each decade. Each decade, the population count provides the data for reapportioning seats among the states in the House of Representatives and Electoral College, and for redrawing district boundaries for seats in the House, in state legislatures, and in local legislative districts. In Canada, a full census is taken during the first year of every decade and an abridged census is taken during the sixth year of the decade. The population data are also used to apportion seats among the provinces in the House of Commons and to draw electoral districts.

Most nations create a permanent national statistical agency to take the census, such as the US Census Bureau or Statistics Canada. The agency in charge generally undertakes a public review process to determine the questions to be asked. The questions vary from nation to nation depending on the particular political and social history and conditions of the country. Most censuses include basic demographic information such as the age, sex, educational background, occupation, and marital status of the individual. Race, ethnic or national origin, and religious affiliation are important questions in many nations. Further questions can include the person's place of birth, relationship to the household head; the individual's or the family's income; the type of house the household occupies; and whether the person is a citizen, has moved in the past 5 years, or speaks a particular language. Questions that are quite routine in one nation may be seen as quite controversial in another, depending on the history of the country. Americans do not ask questions on religious affiliation on the census since it is considered a violation of the First Amendment right to freedom of religion. Other nations, such as India, do collect such information. Questions on the number of children born to a woman were quite controversial in China in recent years because of the emphasis on the one-child policy of population limitation. In the USA, asking a question on income was considered controversial in 1940 when it was first asked. It is no longer as problematic. Questions change in response to public debate about the state of society. Americans wanted to know which households had radios in 1930, and introduced questions on housing quality in 1940. Canadians ask census questions on the unpaid work done in the home.

The standard nineteenth and twentieth century method for taking a census encompassed several phases. The first involves designing the procedures for the census, planning the questions to be asked, and created the field operation to staff the census. The statistical agency first divided the country into geographical subdivisions to be counted, and made maps and address lists, and prepared instructions for the local census takers. In most countries, this phase requires hiring large numbers of temporary workers (enumerators) to do the counting, or calling upon other government employees at a local level, such as schoolteachers, to conduct the count. The central statistical agency prepares and prints the questionnaires, and distributes them to households either through the mail, or by delivery by the enumerators.

During the second phase of the count a responsible adult or household head in every household, family, or equivalent institution is asked to fill out the form or respond to the enumerator and supply the required information about each member of the household. Questions for all people usually include a brief set, on a 'short' form, for example, name, age, sex, racial or ethnic status, marital status, and relationship to the household head. Interest in collecting more information on the characteristics of the population tended to burden the census form with additional questions over time, and thus increase the cost and logistics of the census. The development of probability sampling methods in the mid-twentieth century alleviated some of these issues and resulted in a shift in questionnaire design, which permitted census officials to sample

a portion of households to receive a more complicated or 'long' form questionnaire. A sample census questionnaire generally has many detailed questions on the individual's work status, income, housing, educational background, citizenship, and recent moves.

During this phase, either the person who fills out the form or an enumerator is responsible for making sure the completed questionnaire is delivered to the statistical agency for processing. The respondent may deliver the form by mail, or to the enumerator in person or by phone interview. In the 2010 census round, some countries have permitted respondents to answer the census electronically on the web.

In the third phase, the statistical agency enters the data onto a computer and adds up, or tabulates the responses for the nation, states, or provinces, and cities, towns, and other local jurisdictions. The agency also cross-tabulates the answers, reporting not merely on the number of people in a local area, but on the number of people, for example, in 5-year age cohorts, for each sex, for local areas. The agency only publishes the tabulated results of the count, and keeps the individual responses confidential. In the USA, individual census responses are stored at the National Archives. After 72 years, the original forms are opened to the public for use. These original responses are frequently used by people researching the history of their families.

Through most of the nineteenth century, the census tabulations were tallied by hand. Hand tabulation gave way to punch card and mechanical counter/sorter tabulations of census data from 1890 through the 1940s and electronic computer tabulation thereafter. Until the 1980s, statistical agencies published census results in large volumes of numeric tables – sometimes numbering in the hundreds of volumes. Since then, census results have become available electronically, on disc, magnetic tape, CD-ROM, or the Internet. The choice of census technique for a particular country is the result of its social and political traditions and technological capacities. The US census is highly automated, and is primarily conducted by mail. Canada sends enumerators to deliver the census form to each household; the household head fills it out and sends it in. Other nations use even more labor-intensive techniques of collecting and tabulating the data. In October 2010, for example, Argentina declared a national holiday and required that each household have a person available to answer questions from the legions of enumerators deployed that day.

National Traditions

The United States

The US census was mandated in the 1787 Constitution. At the time of the American Revolution, the framers faced many problems of uniting the 13 separate colonies into a national government, including how to allocate political representation among the states, and how to levy taxes.

The initial government structure under the Articles of Confederation gave each state one vote in Congress and required the states to collect taxes for the national government. This proved unsatisfactory since the states were of widely different sizes, tax capacity, and cultures. The 1787 Constitution derived the sovereignty of the state from the 'people of the US' and created a bicameral legislature with representation in the Senate based on the states; and representation in the House of Representatives based upon the population of each state. The Electoral College was composed of electors determined by summing the House and Senate members for each state. The decennial census was designed to provide the population figures for apportioning the seats in the House according to population. 'Direct taxes' levied on the states were also to be apportioned on the basis of population (Anderson, 1988).

At the time, a racially based slave labor system also existed, and almost 20% of the American population were enslaved African-Americans. The framers debated whether slaves were 'persons' or 'property' and thus whether states should receive representation for their slave populations. The southern states where slavery dominated did not consider the slave population for purposes of apportioning their state legislatures, but they did consider slaves property for tax purposes. The framers could not find an easy solution to this dilemma, and developed what came to be called the Three-Fifths Compromise, which 'discounted' the size of slave population as equivalent to 60% of the free population when determining the apportionment of the House. The Three-Fifths Compromise thus required a separate count of slave and the free, mainly white, population. The Constitution also specified that 'Indians not taxed,' that is, those Indians who were not considered part of the civil society were not to be counted in the census. The Three-Fifths Compromise was abolished with the abolition of slavery after the Civil War; the tradition of accounting for the various racial groups in the population continued after abolition.

The first census was taken in 1790. Assistant US marshals were instructed to travel the country and ask six questions at each household: the name of the family head; and for each household, the number of free white males aged 16 and older; the number of free white males younger than 16; the number of white females; the number of other free people (the free colored); and the number of slaves. They totaled the figures for their local jurisdiction and sent them to the US marshal for the state that in turn totaled the figures for the state and sent them to the President. The first American census counted 3.9 million people.

In later years, the census became more elaborate, with more questions asked, and more data published (Cohen, 1982). In 1850, Congress mandated a census schedule (form) with a line of questions for each person, including their name. A temporary Census Office, as it was then called, was set up in Washington to add up the tables of responses and publish the results in large volumes. By 1880, when the American population topped 50 000 000, the census was still being compiled by hand, using a primitive tally system. In 1890, the Census Office introduced machine tabulation of the responses, and each person's answers were converted to codes punched in Hollerith cards, a precursor to the IBM punch card. The cards were then run through counting machines. This innovation was the beginning of modern data processing and led to further innovations in tabulating large amounts of data. By the 1940s, the Census Bureau commissioned the construction of the first nondefense computer, UNIVAC, to tabulate the 1950 census. By the late 1950s, the Census Bureau dispensed with the punch cards and developed an electronic scanning system, called

FOSDIC, or Film Optical Scanning Device for Input to Computers, to read the answers on the census form and input the data to computer (Eckler, 1972).

In 1940, the US began to collect some census information from a sample of the population, and slowly shifted the detailed questions on the census to the long form asked of only about 15–25% of households. In 1970, the American census became primarily a mail enumeration, as the Census Bureau developed automated address files for the country. As of the year 2000, over 90% of the roughly 100 000 000 residential addresses in the US received the census form in the mail. If the Census Bureau did not receive a response, it sent an enumerator to determine if the address is correct and get the information from the household at the address.

In the late 1990s, the Census Bureau began to experiment with a new method of collecting long form information through 'continuous measurement' or 'rolling sample survey.' The American Community Survey was tested in the 2000 census and it replaced the census long form in the 2000s. Annual national-level household data became available in 2005. Each month, a sample of 250 000 households and group quarters receive an extensive mail survey and return the questionnaire by mail. If the respondents do not return the survey, the Census Bureau follows up with a personal or phone interview to complete the survey. The results are tabulated and results for large geographic areas are reported annually. Smaller jurisdictions receive results rolled up from the results of 3 or 5 years of data, depending on the size of the reporting area. The official population of the United States at the 2010 census was 308.7 million.

Canada

Regular decennial censuses began in 1851 in Canada. The British North America Act of 1867 required that the census provide population counts for the apportionment of representation in the House of Commons among the four provinces of Ontario, Quebec, Nova Scotia, and New Brunswick, and for the periodic readjustment of the boundaries of electoral districts. The first census of the Dominion was taken in 1871, and counted 3.7 million people.

The first Canadian census after Confederation was also a very elaborate affair, collecting information on agriculture, livestock, animal products, industrial establishments, forest products, shipping and fisheries, mining, and public institutions as well as on population. Canada was primarily an agricultural nation at the time, and the Department of Agriculture conducted the census. In 1905, the census bureau was made a permanent government agency in the Agriculture Department. In 1918, an independent Dominion Bureau of Statistics was created with oversight for taking the census and collecting other statistical information, headed by a Chief Statistician. In 1971, the bureau was renamed Statistics Canada. Canada has a centralized statistical system, with all major statistical work conducted in the same agency (Worton, 1997).

Canada began to conduct sample surveys along with the full census in 1941, introduced a quinquennial census (a census on the sixth year of the decade) in 1956, and self-enumeration in 1971. The population of Canada in 2011 was 33.5 million.

Great Britain

The first Parliamentary proposals for regular censuses of population in Britain date to the mid-eighteenth century, but they did not lead to the institutionalization of census taking until the end of the century. In late eighteenth century Britain, the publication of Thomas Malthus' *Essay on the Principle of Population* and concerns that the population was declining led Parliament to pass a bill "for taking an Account of the Population of Great Britain and of the Increase or Diminution thereof." The first count was taken in March 1801 by the Overseers of the Poor under the direction of former clerk of the House of Commons, John Rickman, and counted 9 million people. Census taking continued every decade afterward except for the cancellation of the 1941 Census during the Second World War. In 1837, the General Register Office was organized. The decennial census was made a responsibility of the GRO and used the administrative structure of the registration districts to organize the field portion of the count (Wrigley, 2011).

The 1841 census introduced individual-level enumeration. The mid-nineteenth century census was particularly influenced by the ongoing medical and public health work of the GRO leaders such as William Farr. It therefore developed detailed data on occupation, age, and locale for the denominator data required for the publication of mortality and other statistics (Glass, 1973; Nissel, 1987; Higgs, 2005). Machine tabulation of the census was introduced in 1911. The 1920 Census Act established a permanent legislative mandate for the census. Sampling was introduced in 1951 by way of the analysis and publication of results from a 10% sample of the complete 1951 forms. In 1961, the census used a short form for the entire population and an additional long form for a 10% sample. In 1966, a 1 in 10 sample count was taken. The results of the 1961 census were computer tabulated. By 1966, the Census Office had its own computer facilities. The population of the United Kingdom in 2011 was 63.2 million.

France

France established a population registration system in the late eighteenth century, and began a tradition of quinquennial census taking under Napoleon in 1801. The first census counted a population of 33 million. For much of the nineteenth century, the administration of the count was local with a small national office (*Statistique Generale de la France*) publishing the results tabulated locally. Individual forms were used in Paris starting in 1817; by 1876 the entire country used three standardized forms: one for the individual, one for the family or household, and a third for the building enumerated. Tabulation was done locally until 1896 when Lucien March introduced machine tabulation. The French pioneered in the analysis of occupational statistics derived from the census as a means of understanding the evolution of the economy from an agricultural and artisan basis to one characterized by professional qualifications and employees with credentials. In 1946, after World War II, the French National Statistical Agency was titled *Institut National de la Statistique et des Etudes Economiques* (INSEE) (Desrosieres, 1991).

In the 2000s, France restructured its population measurement system, and replaced the periodic census with a continuous measurement sample survey. Since 2004, local officials count the population on a rolling basis. In municipalities under 10 000 population, a 20% sample is collected annually; the entire population is counted every 5 years. In municipalities larger than 10 000, an 8% sample is surveyed annually, achieving 40% coverage over 5 years. INSEE tabulates and publishes annual reports from the samples. The population of France in 2011 was 65 million (Clanché, 2011).

Issues

Censuses provide important information about the population of a country, and can become embroiled in political or social controversy simply by reporting information relevant to ongoing issues in the society. Complaints about the census generally involve concerns about the accuracy of the count, the propriety of particular questions, and the uses to which the data are put.

Censuses require public understanding, support, and cooperation to be successful. Concerns about government interference with private life can prevent people from cooperating with what is an essentially voluntary counting process. People may be suspicious of giving information to a government agency, or may object that particular census questions are invasions of privacy.

When such public trust is lacking, people may fail to participate. In recent times, individuals doubled up in illegal housing units, undocumented immigrants who do not reside in the country legally, or individuals who do not wish to reveal their economic or social situation to a government agency, can be reluctant to respond to a census. In the most serious challenges, people claim the results will not be held in confidence and that census should not be conducted at all. During World War II, census records and population registration records from countries occupied by the Nazis, for example in the Netherlands, were used to identify Jews for detention, removal, and extermination. The effect of such use was to undermine the legitimacy of the census after World War II. In the Netherlands, which took its last regular census in 1971 and collects population information through other mechanisms, the legacy of the Nazi era was one of the major justifications for ending census taking (Seltzer, 1998).

At the other side of the spectrum, political challenges can be made to the census if the census does not count the population well enough. All censuses contain errors of various kinds. Some people and addresses are missed. People may misunderstand a question, or fail to answer all the questions. Census officials have developed elaborate procedures to catch and correct errors as the data are collected, but some errors tend to remain. Since census results are often used to allocate seats in legislative bodies and government funds, such errors, particularly undercounts, undermine the credibility of the census as an allocation mechanism.

In recent years, developments in statistical analysis have made it possible to measure the accuracy of censuses (Choldin, 1994; Anderson and Fienberg, 2001). Census results may be compared with population information from other sources, such as the records of births, deaths, and marriages in vital statistics. Census officials can also determine the level of accuracy of the count by conducting a second, sample count (a postenumeration survey) shortly after the complete census, and then matching the records of the sample and the census. Census officials estimate who is missed, and who is counted twice or in the wrong geographic location, and use these estimates to evaluate the overall accuracy of the count. The United States Statistics Division (2011: 22) reports that 26% of the countries responding to their survey reported that they would use their evaluation results to adjust the published census figures for the 2010 census round.

In the USA, people who live in cities, the poor, and minorities tend to be undercounted relative to the rest of the country. From 1970 to 2000 officials representing such undercounted jurisdictions claimed that these jurisdictions suffered loss of political representation and government funding since the apportionment and funding formulas are based on incorrect data. Mayors and leaders of civil rights organizations pressed for adjustment of the census results, and filed lawsuits to compel adjustment of the enumeration. The courts have permitted adjustment for some census uses but to date the Census Bureau has not produced sufficiently robust adjusted census results to justify supplementing or replacing the results of the door to door count.

Calls for Future Innovation

The emergence of digital technologies for collecting and reporting information is posing both new challenges and new opportunities for the census as an institution. On the one hand, increasingly wired and mobile populations question why governments need to spend substantial amounts of scarce public funding on a population count, when existing digital records might be able to provide the relevant population information. Several nations, including Canada's 2011 census and the US American Community Survey, are experimenting with electronic response methods for data collection. Planning for the 2020 census round includes proposals for integration of digital administrative records with sample survey methods to produce a cheaper and more efficient census operation. These proposals are being tested to determine if they produce data tabulations of sufficient quality to replace traditional methods.

Perhaps paradoxically, the same digital revolution is also giving new life to historically collected census data, both tabulated published results and the microdata if they have been preserved and archived. Large-scale research projects such as IPUMS USA and IPUMS International promise to retrieve and harmonize microdata from centuries of censuses from around the world for researcher use. Geographic information system technology is permitting historical analysis of tabulated census data from the past in projects such as Social Explorer.

Center–Periphery Relationships

Ulf Hannerz, Stockholm University, Stockholm, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Center and periphery, and related conceptual pairs, have been prominent in the social sciences since the mid-twentieth century. Some such pairs suggest a more consensual relationship, others portray conflict. The emphasis may be more on political economy or on cultural influence. Centers may rise and fall; peripheries may be involved with one or more centers. With increasing global interconnectedness, there is a greater differentiation of transnational center–periphery relationships.

Concepts of center and periphery became increasingly prominent in the social sciences during the second half of the twentieth century. They were of diverse origins and entailed varied emphases, but these differences have not always been obvious in continued use. There has actually been a cluster of related conceptual pairs: center and periphery, but also core and periphery, metropolis and satellite, and metropolis and province. But they have not been mere synonyms. Moreover, in obscure and perhaps treacherous ways, ideas of center and periphery may occasionally have overlapped in social thought and discourse with other classical contrasts, such as modernity–tradition or urban–folk.

The sociologist Edward Shils had a major part in introducing the center–periphery pair of concepts into the vocabulary of academic social science (cf Greenfeld and Martin, 1988). His paper 'Center and Periphery' originally appeared in 1961, but there was a close affinity between it and several of his other publications in the same period. The overall conception of society and culture in Shils' perspective was consensualist; but not, he asserted in a later comment, as merely a facile expression of the mood of the era. In his view, the importance of consensus to social life had been underestimated (Shils, 1975: p. xi). Thus he concentrated on notions such as 'tradition,' 'ritual,' 'deference,' and 'charisma.'

Notably, in his 'Center and Periphery' paper, these two terms were used in a metaphorical sense; centrality had 'nothing to do with geometry and little with geography.' The center was identified with what was ultimate, irreducible, and sacred in the realm of symbols, values, and beliefs; it was also identified in the realm of action with those roles and institutions which embodied such cultural understandings and were most actively engaged in propagating them. Yet in 'Metropolis and Province in Intellectual Life,' published in the same year, the facts of uneven spatial organization which are now usually linked to concepts of center and periphery become clear, and are set in what we would now describe as a transnational context. Drawing on his study of the situation of intellectuals in India, Shils argued that in their minds, people have varyingly extensive maps of the world significant to them, and that a major feature of such maps would be their portrayal of one's qualitative proximity to or distance from the metropolis (Shils, 1972: p. 356).

In the former of these two papers, then, the center is a locus of excellence, of grace; the periphery defers to it. In the latter, the metropolis is a center of vitality, a seat of creativity. The province, on the other hand, Shils notes, is frequently taken to be in itself "rude, unimaginative, awkward, unpolished, rough, petty, and narrow" (1972: p. 357). Cultural salvation lies in an involvement with the metropolis. The choice seems to be one between impoverished autonomy and enriching dependence.

If Shils was a theorist of consensus and cultural authority, the metropolis/satellite and core/periphery pairs, as inserted into the debates of the 1960s and 1970s, pointed in an entirely different direction, resonating with another political mood. 'Metropolis' and 'satellite' were the terms used by the economist Frank (e.g., 1967), who had spent much of the 1960s in Latin America, studying what he described as the development of underdevelopment, and engaging with the growth of 'dependency theory.' Then in the 1970s, introducing 'world-system analysis,' with its emphasis on changes in a global system since the late Middle Ages until the present, the sociologist Wallerstein (e.g., 1974) contrasted 'core' with 'periphery' (but inserting a 'semiperiphery' category as well). Both Frank and Wallerstein were primarily concerned with political economy, and with the expanding control and exploitation of the material resources of the 'periphery' or 'satellite' on the part of the 'core' or 'metropolis.' In both instances, the emphasis was on conflict and domination within a global order.

The points of view represented by Shils, on the one hand, and by Frank and Wallerstein on the other, seem not often to be brought into direct confrontation, although over the years, they may have come to interact and blend with one another. By now, when center–periphery concepts are more passingly referred to, it is not always entirely clear which of the varieties is involved; if not some combination of them. Yet there is a field of tension here between studies focusing on distributions of material assets and the exercise of power on the one hand and studies of culture on the other; between views suggesting consensus and views emphasizing conflict; and between views treating the social organization of meaning and meaningful forms somewhat in isolation and other views which insist on setting it in the context of political and economic structures.

Probably all would accept, however, that centers and peripheries imply each other. We are dealing with relational phenomena: there is no center without periphery, no periphery unless there is a center. The particular way the center is a center is also reflected in the way the periphery is a periphery.

Levels and Varieties

Our conception of center–periphery relationships here is that they are relationships of inequality existing in geographical space. Such relationships, however, have been defined at very

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12031-8

different levels of specificity. During the latter half of the twentieth century, especially in the Cold War era, the world was understood to be divided into three main segments – one Western and capitalist, one Socialist, and one 'developing' and postcolonial. Here, the First and the Second Worlds had their internal center–periphery structures. The Third World, on the other hand, may have had these, but also tended to be seen rather more as a periphery in its entirety, to one First or Second World center or other. At present, the extreme macroview may be that of a center Global North and a peripheral Global South. Much of the cultural and political debate over center–periphery relationships has remained mostly at such levels of identification. Notions such as Orientalism, Occidentalism, and Eurocentrism refer to understandings and representations of self and other in the context of these large-scale center–periphery structures.

Alternatively, identifications may indeed be made at the national level: the United States or France is seen rather more as centers than Sweden, Romania, or Burkina Fasso. In other instances, centers are yet more specifically placed. Nations and regions may have their own centers in particular localities. In the study of historical civilizations, there is frequently an emphasis on centers as sites combining political power with complex ritual life and elaborated knowledge systems in the hands of specialists. A well-known paper by the anthropologists Bernard Cohn and McKim Marriott (first published in 1958), for example, delineates the complementary roles of centers and networks in the integration of Indian civilization (Cohn, 1987: p. 78ff.). In related mid-twentieth century work, as Redfield and Singer (1954), also anthropologists, discussed the cultural role of cities, they described the dynamic relationship between the 'great tradition' of early urban centers and the 'little traditions' of the surrounding peasant societies. The emphasis on the symbolic authority of the center here is clearly reminiscent of Shils' view.

Yet Redfield and Singer also noted that later urban centers, rather than refining particular local traditions, are often at the crossroads of the world, bringing together diverse traditions and serving as communication nodes for wider areas. In this the authors adumbrated recent interest in the role of particular cities in contemporary transnational center–periphery relationships. 'World cities,' such as New York, London, or Paris, may be seen as generalized, multipurpose centers, combining various kinds of power and drawing the attention of the periphery for many different reasons (Hannerz, 1993; Knox and Taylor, 1995). The contemporary global structure of center–periphery relationships, however, can be understood as more internally varied. Cities may be centers in particular ways to particular people, dispersed in a transnational periphery – Rome to the Catholic world; San Francisco to gay people not only from elsewhere in the United States, but also from other continents; Memphis, Tennessee, to friends of country music. As we see, attachments of very diverse kinds are involved. This means that the same people in the periphery may well be involved with several, noncompeting centers for different purposes. Yet centers of the same type can also compete in the periphery.

How do centers become centers, even drawing attention across national boundaries? Some are centers for mainly historical or mythical reasons, because something occurred there once in the past, or occurred there first; or because the memory of a charismatic figure is preserved there. They belong on the map of the significant past, or of eternal truths. Often they are intensified as centers at particular points in a ritual calendar. Many 'centers of pilgrimage' have such characteristics. Other centers are very much of the present. They draw attention and stimulate imagination from afar because they are 'where the action is' now, with regard to one or more lines of human preoccupation. The contemporary proliferation of center–periphery relationships of transnational reach is undoubtedly related to a greater ease of transportation and communication, making centers easy to get to, and easy to stay in touch with. As the participants, practitioners, adherents, activists, and employees of more subcultures, life styles, ideologies, occupations, or corporations use new means to extend their circles out of local or national habitats, new far-away centers are discovered, or even made. As more diasporas are generated by more migrants, old centers may also be reaffirmed, from further away.

A significant part of what has happened in world center–periphery relationships in recent times also seems to involve the ways in which the periphery helps make the center what it is. As a center comes to be recognized, it may draw to itself the most committed of the periphery, as immigrants, tourists, participants, contributors, observers, and commentators. Thus the periphery not only adds to the outside reputation of the center, but may also contribute directly to the richness of its internal life. As the center is in the periphery, so to a degree the periphery may establish its presence in the center.

Center–Periphery Diffusion

In part, it may be in the passage of culture from center to periphery that the two parties to the relationship manifest themselves. In the clearest case, the center would be always the donor, the periphery always the recipient – the center is active, the periphery is passive. Yet even if the imbalance is not quite so great, some measure of net cultural export would appear to be one conception of center–periphery influence. What is prominently involved here, consequently, is diffusion.

In a wider arena of debate about the effects of global interconnectedness, since mid-twentieth century, the preoccupation with cultural diffusion from center to periphery has often been expressed in one or the other of two ways. Post–World War II modernization theory offered a forecast of where the world was heading – where the West actually already was, more or less, and where the rest would follow, with some assistance from the center. When not drily 'value-free,' modernization theory tended to take a positive view of the changes in question. The other major way of describing cultural diffusion on a global scale vas less favorably inclined. The term 'cultural imperialism,' as Tomlinson (1991: pp. 3ff.), has pointed out in a review, is a combination of two complicated concepts into one, with a considerable ideological charge. It has tended to refer to a growing dominance of western, and especially American, media and consumer goods in other parts of the world. Coca-Cola, McDonald's, and Barbie dolls have become the predictable pieces of evidence in a genre of cultural critique. Both the early form of modernization theory

and the critique of cultural imperialism thus tend to offer global homogenization scenarios; implying, forecasting, or warning of the end of cultural diversity.

Such scenarios, however, have been increasingly often contested. There has been a growing attention to the multicentricity of culture, to crisscrossing cultural flows, and not least to instances of cultural counterflow, from periphery to center. While some net asymmetry of flow may yet be undeniable, many commentators have also become less inclined to accept the assumption of passive reception at the periphery. They are much more likely to see an active periphery engaged in managing diffusion from the center: the periphery accepts this, rejects that, modifies one thing, and synthesizes something else with items from its own local cultural inventory. Metaphors of creolization and hybridity summarize this combination of cultural diffusion with creativity at the periphery.

Moreover, it has been argued that a periphery engaging with more centers can be in a quite different situation from one linked to only a single center – in a way it may even be in an advantaged position compared to these centers. Instead of being complacently self-sufficient and self-centered, as these often are, the multicentering periphery can at best go beyond eclecticism to work out its own cosmopolitan synthesis of its selections from the centers. Here, then, creativity draws on the peripheral condition.

Soft Power

A recently popular concept which may be placed in the context of center–periphery relationships is that of 'soft power,' originally proposed by the American political scientist Nye (2004). Here is a notion which links politics with culture. Soft power is understood to stand in contrast to that which is hard power: command power, not least military power. It co-opts rather than coerces people; "if I can get you to *want* to do what I want, then I do not have to force you to do what you do *not* want to do." Nye, concerned largely with the role of American power and its varieties in the world order, points to the different ways American values can be projected to support the country's global leadership role, but gives some special emphasis to the diffusion of American popular culture. This line of thought, then, portrays Washington and Hollywood working in tandem to build a global center–periphery structure.

One reason why the idea of soft power has had a wider appeal, however, is that it can attract commentators, and political actors, also in countries which have less of a real opportunity to choose between hard power and soft power. On a global or regional basis, countries or other entities can hope to be able to convert cultural penetration or persuasive power into political influence. This view, consequently, goes with a more multicentric understanding of relationships between centers and peripheries.

One factor in the global cultural order which may be linked to a notion of soft power is that of language, and language diversity. The Dutch sociologist De Swaan (2001) has delineated the characteristics of the contemporary 'world system of language.' It is a system with three major tiers; and what is important is less how many people use a language as their first language, their 'mother tongue,' but how many can use it as a second language. This is what at present makes English more important than any other language, the only language in the first tier. In the second tier, there are a number of languages with many native speakers, but also sizable numbers of other speakers: French, Spanish, German, Russian, Arabic, Chinese, and some others. Then in the third tier, there are innumerable languages, including national languages with few speakers outside the nation.

Languages have certainly not reached their places in this hierarchy as a matter of chance, or through some intrinsic merit. The world language system is an accumulated, although changing, product of history, politics, and commerce. Yet as it is, it may have some influence of its own. The present situation is one where a very considerable proportion of the people of the world can understand spoken or written English, and even though at least some of those who use it as a second language use it actively enough to make their voices heard, this means that those parts of the world who have it as a first language gain a certain advantage. It is easy to pay attention to them. What is said and written in other places, in other languages, becomes less widely accessible. Somewhat paradoxically, this center–periphery structure of language use is also strengthened by the distribution of translations. While it would seem that the widespread English-language skills would make translations of written work from this language into other languages somewhat superfluous, and translations into English would be more desirable, the fact is that translations from English into other languages are much more common.

Mixed Feelings

It is in the nature of their asymmetrical relationship that center and periphery take different views of it, and may even be differently aware of it. A periphery has to attend to its center. The center for its part may at times be preoccupied with its internal affairs, and may not have a clear grasp of the more widely dispersed consequences of its actions. The periphery tends to have a more developed, more detailed, sometimes more imaginative and sometimes more knowledgeable idea of the center than vice versa. (This is obviously a spatialized aspect of the general tendency that the subordinate knows more about the dominant than the other way around.)

Emotions may be attached to such linkages. Center–periphery relationships often do not leave people cold, passionless, and neutral. In the consensualist view, centers generate warm, deferential attitudes at the peripheries. In a conflict perspective, in contrast, center and periphery are primarily defined by political and economic structures – and we may then see their cultural concomitants at the periphery in the responses to control, coercion, and constraint. Along such lines, the many forms of cultural resistance have been a major theme in the portrayal of center–periphery relationships (also becoming more prominent in Wallerstein's world-systems analysis over time). The periphery may defend itself symbolically against intrusions through a celebration of the self and its local and traditional roots, but there may also be a denigration of the other, an uncomplimentary representation of the center.

Yet the responses of the periphery to the center are not always clearcut. For one thing, claims to center–periphery

consensus now increasingly meet with skepticism. With Gramsci as a source of theoretical inspiration, observers may interpret deference in the more complicated terms of hegemony. Nye's notion of soft power certainly has hegemonical implications. It is likewise possible, however, that people at the periphery may be genuinely of two minds about a center. If ambivalence is a prevalent quality of social life, as Smelser (1998) has argued, perhaps this is even as common a response to a center as any more one-sidedly favorable or unfavorable stance. It may be a place one loves to hate and hates to love. One may feel that good things come from there, and at the same time resent its influence, or what may seem to be its narcissism. Especially those multipurpose centers understood to be 'where the action is,' moreover, may inspire sentiments which are positive, but instrumental or playful rather than deferential. They are among the liminal spaces of contemporary life.

All views of the center, however, and all messy feelings toward it, are not necessarily to be found in any single inhabitant of the periphery. They may rather be complicatedly distributed among its population, and such variations can be the foci of intense debates and conflicts structuring local life at the periphery.

The End of Center–Periphery Relationships?

With some frequency, one now hears voices criticizing center–periphery concepts, or proposing the decline of center–periphery structures. It is said that the world economy is increasingly decentered (see e.g., Lash and Urry, 1994: p. 4). Human life, it is also argued, is increasingly deterritorialized. People move quickly between places, being rooted in neither of them, and have relationships which belong in no place in particular. 'Critical masses' for cultural elaboration may be built up in cyberspace, and do not require local face-to-face contacts. As would-be centers and would-be peripheries are closely in touch, by way of electronic media or jumbo jets, the 'cultural lag' which divided them in the past is no longer there.

Even if they are often closer to futuristics than to the really existing world, there may be something to such arguments, At times, however, both the concepts criticized and the alternatives to them would need to be elaborated more precisely. Indeed, we must be sensitive to the ambiguity of our terms, and to the actual range of variations out there. Asymmetries may indeed only be relative, culture flows are not entirely one way, the world is crisscrossed by more symmetrical relationships as well, and there are many centers, and many kinds of centers, rather than only one. Centers also rise and decline. In the early twenty-first century, some of the large countries of that Global South – China, India, Brazil – are turning into major economic powers. It remains to be seen what global cultural influence will go with that, but one could note that Japan, rising earlier in the world economy, fairly soon thereafter did gain more global attention for its developing popular culture (Iwabuchi, 2002). In some Japanese circles, the hope was expressed that this would be accompanied by more soft power.

Center–periphery conceptualizations, it seems, deserve to be continuously scrutinized and developed, rather than merely rejected. It is notable, too, that the end of centers and peripheries appears often proclaimed by commentators whose own vantage point is at the center; in this case, not a privileged position.

Central Africa: Sociocultural Aspects

René Devisch, University of Leuven, Leuven, Belgium

Abstract

Most authors define Central Africa as the vast area comprising speakers of the different western branches of Bantu. The great diversity of western Bantu populations and traditions has gradually extended, beginning 5000 years ago, from southern Cameroon, into Equatorial Guinea, Gabon, People's Republic of Congo, the Democratic Republic of Congo, and Angola. Side by side with Ubangi and Nilotic speakers, they have moreover spread across the Central African Republic, South Sudan, western Uganda, Rwanda, and Burundi, to eastern Congo, Tanzania, and northwestern Zambia. Whereas the eastern Bantu have specialized in grain growing, the western Bantu adopted cassava and yams for staple foods. The region has been the scene of complex interactions between the local and outer worlds.

In the equatorial forest in the Congo basin and its northern fringe, for centuries decentralized agriculturalists have tended to privilege their patrilocal households as an economic and political stronghold. By the sixteenth century, long-distance exchange economies of textiles and firearms for ivory and local captives may have connected the equatorial forest even with Egypt via eastern Sudan. The savannah regions in the southern and western half of Central Africa saw the emergence of important political leadership roles, including kingship. Their history became tragically bound up with the growth of the Atlantic slave trade. Following Livingstone's and Stanley's trans-African 'explorations,' the 1885 Conference of Berlin legitimized imperial Europe's colonial scramble for Central Africa. From the 1950s on, frustration on the side of those having assimilated the European civilizational capital grew with the glaring contradictions between their 'Whitened' skills and aspirations, on the one hand, and their second-rank position in the colonial institutions, on the other. In the 1970s, Authenticity Movements as well as parody in popular culture cropped up in various newly independent African states and prompted in people a radical shift away from passive assimilation of the White civilizational models; now they urged them to take possession in a militant way of their own history and a dignified self-representation on the world scene.

Most authors define Central Africa as the vast area comprising speakers of the different western branches of Bantu. The great diversity of western Bantu populations and traditions has gradually extended, beginning 5000 years ago, from southern Cameroon, into Equatorial Guinea, Gabon, People's Republic of Congo, the Democratic Republic of Congo, and Angola. Side by side with Ubangi and Nilotic speakers, they have moreover spread across the Central African Republic, South Sudan, western Uganda, Rwanda, and Burundi, to eastern Congo, Tanzania, and northwestern Zambia. Whereas the eastern Bantu have specialized in grain growing, the western Bantu adopted cassava and yams for staple foods. The region has been the scene of complex interactions between the local and outer worlds.

AD 1000–1880

Probably due to its sparse population, Central Africa did not develop the type of domestic markets and specialized local industries as found in West Africa. Until the late fifteenth century, it stayed out of the lines of long-distance communication such as those that had developed from coastal East Africa or along the caravan routes of West Africa. The history of precolonial Central Africa from AD 1000 can be divided broadly into two main regional developments.

With regard to the northern half of Central Africa, comprising the great equatorial forest with its northern woodland fringe and the Congo basin, linguistic and ethnographic data – common 'words and things' (Vansina, 1990) – bear witness to the interaction between the farming and pastoral peoples in the forest and savanna areas north and south of the Equator. The most important hunter-gatherer groups of northern Central Africa were the matrilineal Pygmies, who interacted with their agricultural neighbors and long-distance trading groups (like the salt-making Vili of Loango, and the neighboring copper-trading Tio). The Zaire River and its tributaries have comprised an important corridor for the transmission of cultural influences and systems of government, as well as for the trading economies of the Atlantic zone. The farming in the thinly scattered patrilineal societies of the northern and eastern corner of the rain forest remained for long untouched by the food plants originating from South America and already imported into other parts of Central Africa.

In the central part of the equatorial forest, the Mongo patrilineal societies were strongly influenced by the neighboring agriculturalists to the northwest along the Ubangi and higher up in the Sudan. Mongo Big Men, often combining agriculture and trade, tended to privilege their patrilocal household and patriclan rather than the village community as an economic stronghold and political unit, also by way of matrimonial transactions and cultic and initiatory specializations. By the sixteenth century, long-distance exchange economies of textiles and firearms for ivory and local captives may have connected the equatorial forest even with Egypt.

The savanna regions in the southern and western half of Central Africa saw the emergence of important political leadership roles, including kingship. Depending on the rainfall, the wooded savanna was moderately suitable for agriculture and/or pastoralism. Priests were the guardians of all reproductive resources. The extended family was the focus of physical and spiritual well-being of both living and deceased members of the patrilineage. Lineage chiefs gained control over the

rain-making cults, the territorial custody of hunting traditions, and the collection of tribute. From the fourteenth century, the chiefs gained regional control over iron and smithy work and, particularly from the seventeenth century, over firearms and market-oriented commerce. This as well as their indirect involvement in the Atlantic slave trade made their power paramount over large areas in central Angola and western Congo.

Challenges from the Atlantic and Colonizing Europe

Unlike West and East Africa, Central Africa had not entered the maritime trade prior to the arrival of the Portuguese caravels seeking trading bases, from the 1480s onward. Reports by Portuguese missionaries and merchants as well as occasional correspondence by Western-educated Kongo show how the foreign influence brought radical changes to Kongo kingdom and culture. The kingdom then comprised prosperous farming communities linked to a regional trade of fish and craft goods. From this period, the *nzimbu* shells in the hands of Europeans took on the functions of coinage for the previously unfamiliar purposes of wage payment and marketing.

Portuguese traders carried Mediterranean manufactures to Kongo in exchange for raffia cloth, ivory, dye wood, and copper. The redistribution of these manufactures (such as North African textiles, iron knives, glass mirrors, glass schnapps bottles, glazed bowls, Venetian beads, and glazed china) was controlled carefully by the royal court. Moreover, Portuguese teachers, artisans, lawyers, and priests enhanced the authority of the king and his closest supporters. A number of Kongo were taken to Europe for further education. From the sixteenth century, the history of the southern savanna became tragically bound up with the growth of the Atlantic slave trade. Manpower, rather than landed property as in early modern Europe, was the key to value in the Central African communities. Slave trading of servile subjects and captives gained via long-distance marketing at the Malebo Pool (where Kinshasa would later develop) became the grim solution to local needs for foreign goods. Like any slave-trading society, the Kongo kingdoms and other neighboring equatorial kingdoms became oppressive and fractious, and doomed to collapse.

The Atlantic trade gradually came under the control of the semicolonial Luso – an African community of the Loanda hinterland, Africa's first White colony. The long-distance savanna trade routes probably became avenues for the dissemination of European goods and influence, as well as of the South American crops: maize, cassava, tobacco, and tomatoes. Soon, frontier states such as Matamba and Kasanje as well as a new class of trading entrepreneurs took control over trade relations with the European powers. Following the industrial revolution in Europe, new goods were being shipped to southern Cameroon, Gabon, and the lower Congo. Toward the end of the eighteenth century, with the involvement of French, English, and Dutch merchants, the Atlantic slave trade reached its peak.

Swahili-Arab penetration in northeastern Zambia and southeastern Congo in the early nineteenth century started as trade of guns and powder for ivory and slaves. It would soon overthrow the local chiefs and gain independent political power for itself.

Following Livingstone's and Stanley's 'explorations,' the 1885 Berlin Conference legitimized Europe's division of Central Africa into colonies. The conquest of Equatorial Africa would last until the 1920s before military power, forced labor, harsh rubber exploitation, diseases, and hunger would have decimated half of the population and broken local resistance. Colonial rule gradually deprived local societies of the institutional ability to confront the exploitative forces and exogenous 'civilizing programs' imposed upon them. In the views of the colonizing masters, the bringing about of philanthropic medical provision and widespread school education in the colonies was an essential feature in the international justification of political and economic colonialism. The colony's extractive economy, directed at the 'so far unutilized resources' and relying on mandatory labor in lieu of tax payment, as well as its transport and communication technology were to open up the remote areas to the larger world scene. They were to 'uplift' and integrate the local populations in the new era of 'universal civilization and progress.'

Bantu traditional rule was deeply alien to the colony's display of order. Colonial state power was imposed through regulations, enticements, and direct interference, as both text and texture, absorbing and domesticating people and events by the very acts of *writing* and administrative *ordering*. The textual economy disassembled and inserted local realities into panoptical recording and regulation. The management of people's civil identity and geographic confinement was achieved through the identity cards and mandatory 'passbooks.' Records of marriage, descent, settlement, and land use were meant to bind the populations geographically, and were authoritative for the succession to chiefly titles and for settling matrimonial and family disputes. On the other hand, such regulatory documents were intended to modernize society by freeing the so-called *évolué* from customary collectivism. Population censuses, together with geographic and linguistic-ethnographic mapping and recording of data, allowed for a compartmentalization of languages and ethnic groups.

Unlike the nineteenth century bureaucratic nation-state in the West, the Bantu political traditions of Central Africa do not draw their inspiration from orders of visual representation and architectonic spatial models. They are molded by organic, hydraulic, and/or animal-totemic metaphors informing political networks and strategies as an order of events, forces, sources, and relations. Membership of and alliances between particular social groups are not primarily tied to a geographic partitioning but to blood ties and to the mythical or primal space-time order in line with the constant cosmogenetic reenactment of the reproductive and hierarchical weave between the founding ancestors, their foundational and migratory exploits, and their multiple descendants.

The functions of traditional political title holders were, and are, being thought of as prior to, and the source of, all life forms as well as the guarantee of their order. A chief represents and surpasses his subordinates by his twofold function. First, like his totemic animals (leopard, eagle, and crocodile), he is a conqueror. Through enthronement, the ruler embodies the

founding ancestors and represents the primal space-time order initiated by the immigration of his ancestral people and their conquest of the land. Through his body, in particular, his keen perceptiveness and the nightly forces that he shares with his totemic animals, the ruler impersonates the founding ancestor. He imposes the qualities of a perennial hierarchical social organization, territorial unity, and moral order on his society. Second, the chief acts as the androgynous lifegiver or mediator of the (re)generative processes between the land, society, humans, and the 'the primal womb' in the earth. His rule is thus one of cosmic and physical regeneration, guaranteeing human, agricultural, and social reproduction, and instituting commensality and sharing in his territory. In this diurnal ordering role, the chief protects his people from the nocturnal antirule of envy, theft, sexual abuse, and sorcery. The elders, through councils, ceremonial exchange, and authoritative speech, extend the regenerative capacity into the daily weave of events and relations uniting kin groups under common rule.

In the Christian mission stations or in the plantation, mining, and industrial enterprises, ever larger numbers of individuals and families joined the workers' camps and 'indigenous townships,' set up outside customary rule, on the fringes of White settlements. They thus created new ideological and physical spaces of identity and collective imagination. Indeed, from the last decades of the nineteenth century, Christian congregations set out to work side by side with the concessionary companies and the colonial administration. Their aim was to 'bring civilization and universal salvation to the Dark Continent,' as well as to 'save the individual's soul' through the removal of 'pagan African customs.' While the first decades of the missionary endeavor were directed at the adaptation of Christianity to local society and culture, from the 1930s on, missions became increasingly involved in the social engineering of the townships, echoing the dominant mood of the plantation or mining trusts and the colonial administration. From then on, church authorities designed paternalist programs to educate converts toward assimilating modern skills and dispositions. By the 1950s, the term 'modernization' had become a new banner for the assimilationist option.

In the Belgian Congo, the colonial government had secured the agreement of the missions to manage the schools in exchange for land concessions. Nearly all mission stations developed boarding schools with enough fields, cattle, poultry, and workshops to be self-sufficient. The colonial school presented Western progress as the source of a more dignified identity on the world scene. Vinck (1995) convincingly shows the extent to which, from the 1920s in the Belgian Congo, the school books conveyed the primary symbols and values of the West. By encouraging the pupils to develop a new identity and self-image, these manuals influenced the entire political élite-to-be in postindependence Congo. The concept of state, a key notion in the school books, was the comprehensive, abstract, depersonalized expression of the new power and authority that came to dominate the various spheres of life. According to the manuals, all Whites shared in the power of the state and thus were to be considered as authorities. Colonial school books depicted traditional society and religion as dominated by sorcery and the machinations of the devil.

Endogenization

From the 1950s, among the second generation of those having assimilated the European civilizational capital, the frustration grew with the glaring contradiction between the promises that the colonial master had put before them and their second-rank position in the colonial institutions. A few Christian priests, pastors, and élite got imbued with the Third World emancipation movement enhanced by the rapid decolonization in Asia, the 1955 Afro-Asian Conference in Bandung, the independence struggle in Algeria, the *Négritude* call for the rehabilitation of African cultures, and the Pan-Africanism radiating from Ghana and Guinea.

The militant élite used a triple banner in the battle for decolonization (Devisch and Nyamnjoh, 2011). First, in the terms of the Christian, humanist, and/or socialist discourses of the colonizers, they claimed the right to dignity, social emancipation, and equality. Second, their political aspirations were largely drawing on European ideological discourse associating modern economic development with gradual political emancipation. They thereby became complicit with the modernizing and authoritarian endeavor of the White welfare state and nation-state, however alien it was to people at the grassroots level. Third, in the terms of western Bantu traditions, they favored a palaver model of negotiation, ceaselessly co-opting 'brothers' and 'doing things with words.'

In the 1970s, authenticity movements in various states prompted a radical shift away from assimilation of the White civilizational models, now urging people to take possession in a militant way of their own history and a dignified self-representation on the world scene. Throughout the 1970s and 1980s, artists and customers in the discos celebrated liberation from paternalist and moralizing colonization. Today, people in both the rural and urban milieux have become aware how much their lifestyles, modes of production, and environments are both in rupture with their parental models, and are simultaneously excluded from the current economic and informational globalization of Western consumerist lifestyles. The masses in the poverty-stricken suburbs have been haunted, through television and downtown scenes, by the imageries of ease and extravagance that the transcontinental mass media as well as the few very rich nationals exhibit in fine clothing, expensive cars, and luxury goods. Many are increasingly bitter about their exclusion. However, they do not fail to develop their own proud visions of society and the way things are. In the early 1990s, through the waves of demonstrations and Dead-Town protest manifestations or even uprisings, suburban people counteracted the governmental views on modernization and the neocolonial politics. Irony and parody allowed the populace to deconstruct imperialist twentieth-century modernity.

Suburbanites straddle worlds through hybridity or the imaginary transgression of codes, in particular in the utopian fields of humor, daydream, and language. These are gradually furthering a cultural critique of the postcolonial situation: rather than fighting one another as ill-fortuned or discontented consumers of modern cash goods (increasingly brought in secondhand from the North), people in suburban neighborhoods and rural communities are reexploring their

genuine sense of communality, and their collective memory stored in body techniques and sensuous culture. Hybridity in many cultural expressions blurs the tradition–modernity, Bantu–Western, precapitalist–capitalist oppositions that have been created by the Europeanizing tropes. Songs on the radio today in vernacular languages and along old rhythms, recalling both the collective frenzy and euphoria in the bars of the 1970s and 1980s and village festivities or rituals, are now unsettling the Reformist voices of the (post) colony which had connected city life with French or English speech and etiquette, with school education and the petit bourgeois lifestyle, and with well-equipped biomedical services. The pidginization or creolization of French or English colloquial language, and of narrative styles in songs and newspapers, vitiate modernist master tales about the literate African city dweller and the retrograde and illiterate villager. Thousands of independent prophetic healing churches of the holy spirit, through exorcizing materialist greed and Westernization of public mores, or even state politics identified with the work of *sataani* (the local term for the Christian-imported notion of Satan, referring to those engaged in illegal practices and sorcery), develop a forceful critique of the catastrophic collusion between economic modernization and people's sociocultural dispossession. At the same time, through collective trances and 'Christian' forms of telepathy and clairvoyance in the name of the holy spirit, the prophetic churches explore ways toward domesticating modernizing forces. During the ceremonial offering of money to the prophet and assistant assembly leaders, adepts may circle more than a full hour around the congregation, dancing and singing as if to reenchant one of modernity's most striking secularizations, anonymous cash trade. The offering aims to transform the subaltern's poverty and needs into what is defined as divine grace or healing. The prophetical churches thereby speak back to global capitalism and celebrate their participation in a new economy. They subject the monetary economy to the utopian ideals of equality and solidarity proper to brotherhood and sisterhood.

Abstract

Since the end of the Soviet Union and with improved access to the region, the anthropology (in the Western tradition) of Central Asia has taken off. Recently, there has been greater acknowledgment of local sources, archives, and scholars. Moving from a sense of Central Asia as an isolated area, a variety of approaches have begun to theorize the region as partly integrated with other regions and traditions: Islam, Turkic and nomadic peoples, Southwest Asia, and postsocialist and postcolonial areas. An emphasis on past and current migrations and trading networks to, from, and within the area further stretch the idea of Central Asia and reveal the complex lived experience of ethnic groups – often at odds with nation-state ethnoterritories. Debates continue as to the extent to which clan organization informs current elite politics and pre-Soviet traditions are reemerging intact, in hybrid forms, or were wiped out. The main focus of studies has been on religion, politics, and ethnicity. Further research is needed on new economic and other inequalities, industry, labor, and the environment.

Central Asia is arguably one of the oldest ingénues on the world stage: repeatedly discovered by various scholarly communities, commercial or state powers bent on opening up new ethnographic regions, seeking new resources and reconfiguring geopolitical alliances. Newton (2001) suggested the image of the loose fish to evoke the scramble to discover and make various claims in, and about, Central Asia after the collapse of the Soviet Union as though the area were a blank spot on the map. Arguably, this sense prevails in conceptualizing the anthropology of the region as catch-up (Liu, 2011) for Anglophone or Western style scholarship. The recognition that a wealth of other work exists, however, by pre-Soviet, Soviet, and post-Soviet local scholars has begun to reshape the contours of the anthropology of Central Asia through new translations and critical engagements with historical accounts (e.g., Levi and Sela, 2009), Soviet-era ethnography (Mühlfried and Sokolovskiy, 2012) scholars from the region (Masanov, 1996; Naumova, 1991) and archives (Jacquesson, 2010), following what Stoler (2009) christened the archival turn.

Elastic Area Definitions

While geographical definitions of Central Asia are notoriously variable, overlapping with other categorizations such as Russian Turkestan, which covered the Turkic lands, the author adopts the current convention of Kazakhstan, Turkmenistan, Kyrgyzstan, Uzbekistan, Tajikistan, and Xinjiang (although an argument could be made for including the post-Soviet Caucasus region). It is worth being reminded of the differences of each country plus the specificity of Central Asia and elements it shares with other regions and histories. Indeed, as discussed below, the region often seems to appear and disappear in the same stroke. A few characteristics will serve to frame the remainder of the article. Unlike the steppe, nomadic past of the other states, Uzbekistan has a long history of urban settlement; indeed Tashkent was the main city of Soviet Central Asia in terms of population size and cultural purchase; a point that is, perhaps obviously, contested by other cities of the region. Despite the aridity of Tajikistan and Uzbekistan, much of this land was turned over to cotton monoculture in the last century, which in turn necessitated huge irrigation projects, in part responsible for the Aral Sea's desiccation and environmental catastrophe from which many fled. The mountainous terrain of Tajikistan and Xinjiang, sometimes known as Chinese Turkestan, means only a small area is available for habitation and cultivation. Xinjiang is home to many ethnic groups from the rest of Central Asia, particularly the Uyghurs, a Turkic people with no titular state (Bellér-Hann et al., 2007).

As Roy (2000) observed, Central Asian polities, particularly the Ferghana valley borders between Kyrgyzstan, Uzbekistan, and Tajikistan, appear to have been devised by Stalin with an eye to the necessity for an overarching political entity to keep the peace. Sure enough, with the end of the Soviet Union, civil war broke out in Tajikistan and there have been conflicts in the region since. Border violence following independence has echoes in many other postcolonial settings. Again as Kandiyoti (2002a) noted, Central Asia was distinct economically and politically from other Soviet republics. In eastern European states, such as Hungary and Czechoslovakia, economy and political control were roughly coterminous with the polity and managed locally, whereas the Central Asian states were largely extractive economies or agricultural monocultures (cotton and wheat) effectively controlled by Moscow, via all-Union ministries and local cadres who also directed resources across Soviet space. Technical and professional work was typically dominated by Slavs, presenting an acute shortage of such expertise when many migrated West after 1991.

One further point is the Soviet-era energy network that weaves the Central Asian states together into a curious cat's cradle of interdependency.

One indication that Central Asia is now recognized globally to be as vital an ethnographic region as any other, not just a curious relic shuffling back into life, is the recent overviews in mainstream anthropology journals and handbooks (Rasuly-Paleczak, 2005; Liu, 2011; Marsden, 2013). Ironically then, even as Central Asia has emerged as an ethnographic region, it has largely been through revealing the essential plurality and fluidity of the area, challenging macrolevel accounts, both emic and etic, of nation-state building enterprises on four counts. First, the region is often theorized as an extension of other regions and traditions – often being treated as though

remarkably plastic to the impress of theories cultivated elsewhere. Second, past and present migrations for economic, political, and environmental reasons extend the reach of the region's peoples globally – and certainly challenge anthropological accounts to take such diasporas into account. Third, the coexistence of stateless groups such as the Uyghur and other ethnic groups within nation-state boundaries query the monocultural productions of elites and, fourth, films and the built environment are increasingly being analyzed as a way of engaging with an imagined global audience.

Thus, Liu (2011) suggests following Chari and Verdery's (2009) linking of postsocialist (typically the Soviet Union and eastern bloc) and postcolonial areas, although Kandiyoti points to the limitations, as well as the potential, of extending postcolonial (2002b) and postsocialist (2002a) analyses to Central Asia. Rasuly-Paleczek (2005) shows the advantages of drawing on other Turkic analyses of relationships between tribe and state; Marsden (2012) suggests comparison and integration with southwest Asia and broader imagined Muslim communities. An increasing emphasis on tracking historic and contemporary migrant flows, the changing positions of different ethnic groups within and beyond each country, and the palimpsests of ethnic groups and social practices within cities present sharply different views of ethnoterritories from that presented by nation-state elites, more akin to Appadurai's (1990) notion of ethnoscapes. Finally, a recent interest in political performativity (Cummings, 2010; Beyer et al., 2013) and spectacle, whether events (Adams, 2010), the built environment (Laszczkowski, 2011; Alexander et al., 2007), or films made by or about (Yessenova, 2011; Norris, 2012; *Slavic Review*, 2008) Central Asian states, suggests another avenue for extending the region as government elites seek to brand the nation through monopolizing notions of national culture and tradition speaking both to their own populations and to an imagined global stage. Lane's (1981) classic account of the rites of rulers appears to be holding its own, albeit in a nominally different context.

In the remainder of this article, the author touches on and extends the main themes (covered by these excellent overviews, economics, politics, and religion) ending with topics largely omitted, for want of space, by these essays: migration, gender, industry, labor, the current economic crisis, and environmental challenges. However, the author starts with a brief overview of the historiography and institutional framing of the region.

Non-Western Accounts of Central Asia

Levi and Sela's (2009) anthology of historical sources on Central Asia from the seventh century on shows a sequence of Arabic, Muslim, Turkic, and Mongol encounters via trade and conquest and accounts of the area. The Uzbek dynasties, of the sixteenth and seventeenth centuries, most famously chronicled by Babur, were also described by English merchants, explorers sponsored by Catherine the Great and, later, by players of the first 'great game.' Paksoy suggests that these early forays into linking Turkic Central Asia with Turcology, such as the sixteenth-century Dede Korkut epics translated by Barthold (1894–1936) in the 1930s were suppressed by Stalin in the 1950s as indicative of a potential pan-Turkic polity. The phenomenal resource wealth of Central Asia has long attracted careful mappings of resources: lands, people, flora, and fauna. Shoqan Walikhanov (1835–65) is one of the best known Kazakh scholars of the region, although as a fully signed up member of the Russian imperial army his adoption as one of Kazakhstan's national heroes is perhaps a little strained. Access to Soviet space by Western scholars was restricted, with Central Asian encounters particularly sparse. Lubin's (1985) account of labor relations in a factory in Andijan in 1979 is almost unique as both an ethnography and going beyond religion, politics, and kinship, three topics that continue to dominate studies. Piirainen's (1996) ethnography is a fairly unique and excellent description of a one-company industrial town in Kazakhstan breaking down after 1991. Otherwise, studies of Central Asia by Western scholars were largely limited to macrolevel analyses based on secondary data such as official statistics and archives, as it was in the earlier days of the 1990s, when state formation was of central interest (Smith et al., 1998).

Institutional Framing for Areas and Topics

For anthropologists, institutional and national support concentrated fieldwork in some countries and on certain topics, although not exclusively. Thus, research programs at the Max-Planck Institute for Anthropology have covered property changes (Hann, 2003) and civil religion (Hann, 2006) in Central Asia. The establishment in 1992 of the French Institute for Central Asian Studies in Tashkent, enabled several French scholars to undertake research in Uzbekistan. Elsewhere access continues to be difficult. Tajikistan's civil war 1992–97 and continued devastation has attracted few anthropologists (pace Harris, 2004), although several PhD dissertations are based on the country and Marsden (2012) provides wonderful accounts of Afghan traders in Tajikistan; Turkmenistan is more forbidding yet (see, however, Peyrouse, 2012). So, however much one wants to quibble over the geographical extent of Central Asia, most of the anthropology, in the Western tradition, whether from the East Pacific, United States, or Europe, has concentrated on Kazakhstan, Kygryzstan, and Uzbekistan. Xinjiang, interestingly, has variously attracted scholars of China, Islam, postsocialism, and Turkic peoples and languages.

Property Regime Change

Most accounts of economic change in the 1990s can be aligned with broader postsocialist narratives across the former Soviet region, which focused on immediate economic survival in the aftermath of the abrupt contraction of the state and, with it, the disappearance of support for health, education, basic welfare, and state enterprises. Alongside this, mass unemployment appeared as industry, collective farms, and services were privatized, restructured, or simply ceased to function. Although property regime change is sometimes glossed as the privatization of state assets and services, state disinvestment did not necessarily result in complete transfer of property objects to private control since assets, such as the social infrastructure

belonging to industrial and rural enterprises, were often seen simply as capital draining liabilities. The landscape was therefore one of unclear ownership of property objects just left to rot alongside privatized state enterprises, land, and housing (Alexander, 2004b). To an extent, these concerns were shared with studies elsewhere of other postsocialist states. Unemployment took many forms from 'unpaid leave' to below-subsistence wage levels, delayed wages, payment in kind, and, finally, complete loss of jobs. When not sold off in toto, the nominal transfer of urban and rural enterprises to their workers via shares, often resulted in the rapid consolidation of control by a few, usually previous directors, as shares were exchanged for immediate cash needs or the small patches of land allocated to individuals or families were unable to support a household, especially where seeds, fertilizer, fuel, and markets were no longer provided. Trevisani (2010) also shows how control was kept by the same people, despite reforms, in Uzbekistan's cotton farms. Corruption and embezzlement were widespread (Khazanov, 2012). Nazpary (2001) proposed a theory of systematically created chaos to obfuscate the deliberate dispossession of people who ended up losing out in Almaty in the 1990s. Although casting emic confusions about what was going on as an account of systematic change, it is nevertheless a powerful narrative of the experiences of those who ended up with nothing. Explanations of changing economic conditions often spun on elites; Rasanyagam (2011) proposed the idea of the state continuing to be the fount of resources to be manipulated by emerging elites as part of the informal economy.

The effects of the abrupt cessation of much industry and associated farms and infrastructure were manifold. More highly valued male jobs were also often those that collapsed first, often seeing a shift in women's roles to primary breadwinner as they went to work in bazaars (Yessenova, 2006; Spector, 2008). Kaiser (2005) tracked the *chelnoki* (suitcase traders), initially often women (Werner, 2004) who spread across the newly fixed and newly permeable borders from Uzbekistan and Kazakhstan, or from neighboring countries to trade in Central Asia (Marsden, 2012). The move to previously devalued business and trade represented a profound moral shift; a once peripheral, often illegal, activity, suddenly appeared to be everywhere and championed by elites. Whether or not the recent economic crisis has caused another bout of moral doubt, or has had other effects, has not yet been fully documented; Petric's (2013) recent volume on the longer term effects of destroying livestock in Kyrgyzstan, Yessenova (2010, 2011) on the solidification of property rights, and Bissenova's (unpub) account of Astana's housing boom and bust are exceptions.

Okada (unpub) provides an imaginative analysis of how the labor theory of value was aligned with a gendered Soviet aesthetics in Tashkent. Thus, the most highly valued paintings were on heroic scales and subjects, in oil, hung in public places and created by men; the slightness of watercolors was reserved for women and domestic spaces. With the collapse of state commissioning and the introduction of alternative systems of valuation via foreign markets, watercolors and sketches increased in value and female artists' economic position improved rapidly.

Rural poverty as a result of decollectivization, privatization, and unemployment has been relatively less studied, particularly recently. Shreeves (2002) and Kandiyoti (2003, 2004) consider gender and rural household economies in Kazakhstan and Uzbekistan, respectively. Just as cities were dotted with discarded buildings, many farms were not so much privatized as abandoned to subsistence; men feeling emasculated by the inability to provide and reliance on women (Shreeves, 2002). In a sense, both urban and rural privatizations showed the continued use of standard neoliberal development paradigms and definitions – and their failure to understand how things worked on the ground and therefore to be efficacious in alleviating new forms of poverty. Understanding rural households and economic units in terms of nuclear families, for example, did not relate to collective, multigenerational labor and property regimes (Kandiyoti, 1999). Werner (1998, 1999) also showed that exchanging lavish gifts and feasts continued to be both a major expense and a source of social/financial stability for rural Kazakh families. Since Khazanov's (1984) foundational work on steppe nomadism, Kerven's (2003) and particularly Khazanov's (2012) studies have provided a trenchant account of changing pastoral property regimes in Kazakhstan and Turkmenistan. Now it is rarely possible to survive through pastoralism alone after the rapid disinvestment of state support and continued policy neglect of rural areas, which often led to stock being sold off for immediate needs. Cartels of distributors fix prices and make survival problematic for small-scale wool, dairy, and meat producers. Khazanov states that this way of life has been irreparably broken: economic and social differentiation is growing in rural areas and pastoralism even less mobile than in the Soviet period.

As the initial shock of unfettered market processes faded or became more familiar, anthropological studies have tended to shift away from a focus on property and value to questions of representation, power inequalities, and identity, often expressed through contested notions of ethnicity, religious diversity, and their entailments. In this sense, trends may be seen as mirroring a more general turn in Western left politics from a politics of allocation to a politics of recognition and identity.

Performing Politics: Identity, Clans, and Fluid Ethnicities

The creation and securitization of new nation-states on the basis of Soviet borders is a continuing concern particularly shared by geographers and anthropologists. What ethnography adds is accounts of how ethnic fluidity in the region, arrested by the Soviet emphasis on ethnoterritoriality, resulted in multiethnic areas, or pockets of ethnic concentrations, that sit uneasily with a renewed emphasis on the nation-state as the political container of legitimate power and identity.

At a macrolevel of analysis, Roy (2000) and Smith et al. (1998) provided early accounts of the solidification of Soviet boundaries noting the difficulties with assuming that a nation-state model had any practical salience for understanding either the ethnic composition of each state or the distribution of each titular group. Kazakhstan's titular group, for example, was less than 50% in 1991 with Russian population concentrations in the north. Many of Uzbekistan's

cities were predominantly Tajik speaking, but with different ethnic concentrations within cities. The plurality and coexistence of ethnic groups within countries and cities in particular (Liu, 2012) as well as border regions (Megoran, 2007) emphasize the need for a historical context to understand the different causes and effects of successive migrations to and from the region before, during, and after the Soviet Union.

Thus, the descendants of mass deportations of Koreans, Meshketian Turks, Germans, Tatars, Germans, and Chechyns, to name but some (Oka et al., 2002), to Central Asia in the 1930s and 1940s have taken different paths after 1991. Kazakhs, for example, who left as a result of environmental devastation or Stalinist repressions have been nominally welcomed back as repatriates, but have faced huge economic and bureaucratic obstacles to reintegration, alongside a sense that the motherland is no longer a place and people with whom they can easily identify (Diener, 2009; Werner and Barcus, 2009). The fact that many of Kazakhstan's cities are primarily Russophone (Davé, 2007) adds to the sense of estrangement. While ethnic consolidation has certainly taken place, the notion of 'return' is far from straightforward, equally so for Russians who have either gone to their own alien motherland (Flynn, 2004) or remained in Central Asia as a newly disempowered minority (Laruelle and Peyrouse, 2004; Kaiser, 1998). In contradistinction to many official proclamations that titular ethnic groups have once again come into their kingdom, the prevalence of so many different groups, together with various generational affiliations within such groups, complicates the reception of such pronouncements and how they are enacted. One result is new ethnically based economic and power inequalities alongside the sheer creativity with which people manipulate and move in and out of classifications (Allès, 2005; Finke, 2006; Tishkov, 1995; Finke and Sancak, 2012).

Studies of power relations in the region are largely analyses of how and to whom power was transferred. Alexander (2007a) and Jones Luong's edited volume (2003) discuss the variety of mechanisms used from central to regional and city-level administrations; there are few such microstudies of the institutional and bureaucratic reforms that enabled the control of resources to shift hands (or stay in the same hands) so fast, simply because access to this kind of material is hard to obtain. Rather debates have centered on the extent to which kinship, in the form of clans, and state power is imbricated. In brief, Rasuly-Paleczak (2005) notes that the historical oscillation, and contemporary imbrication, of power between tribes and state forms is characteristic of Turkic polities and therefore a useful heuristic for analyzing Central Asian politics; Schatz (2004) provides the most detailed account of how this has been operationalized in Kazakhstan, suggesting that clan solidarity simply went underground during the Soviet period only to resurface in sufficiently ambiguous form also to be used as an accusation of corruption. Gullette (2010) draws on Kyrgyzstan's 2005 Tulip Revolution to note not only how frequently 'clan politics' is used as an emic term of disapprobation, but also how this obscures alternative political modalities.

Schatz's argument also traces another continuing debate: the extent to which current social forms are new; a return to pre-Soviet structures as a kind of retraditionalization (e.g., Bazin, 2008); a continuation of Soviet organization, which effectively eradicated earlier systems (Trevisani, 2010); and/or a range of hybrid forms depending on the actors and events (Kandiyoti, 1999) – returning once again to the complex fluidity characterizing Central Asia. Three examples illustrate this debate well: national cultural production; the *mahalle* (neighborhood organization); and Soviet territorial borders, which the newly independent states embraced and sought to make more rigid.

It is worth noting that first, cities are often the stage where these affirmations and contestations of power and belonging play out, continuing the Soviet emphasis on cities as the engines of progress (Alexander and Buchli, 2007) and, second, that such debates range from elite policies to everyday encounters. Typically, national legitimation by elites has been enacted in spectacular form through the mass orchestration of celebrations, recalling similar Soviet extravaganzas, such as Adams (2010) describes in Uzbekistan and through recasting the built environment to signal and enact particular political ideologies (Laszczkowski, 2011). Both Uzbekistan's and Kazakhstan's governments encourage a carefully curated version of Uzbek and Kazakh histories, respectively, using a familiar folkloric lexicon (Alexander, 2004a), effectively performing its rights to the land through blood, where the Soviet period was merely an aberrant blip (see Grant, 2001 for a similar discussion of Moscow's new monuments). Kazakhstan's elites endeavor to keep one foot in a romanticized nomadic past, the other in a hi-tec, global/Eurasian future (Laszczkowski, 2011). Liu's (2011) point is important that the Uzbek government has often practiced a foreign policy sympathetic to the interests of its allies but injurious to the Uzbek people, even as it leads celebrations of Uzbek national culture.

The *mahalle* is both a neighborhood and a form of community organization typical of Turkic cities; in Central Asia it is particularly associated with Uzbekistan. Its reemergence in urban politics has been interpreted as a traditional structure that has been co-opted by the new municipal administrations (Trevisani and Massicard, 2003; Rasanyagam, 2009), and an instance of how concentrations of different forms of sociality continue to coexist within one city, Osh, home to Uzbeks excluded from both Kyrgyzstan and Uzbekistan (Liu, 2012).

The rush of the newly independent states to secure and cement territorial borders (Reeves, 2011; Megoran, 2007) points not just to the state work of manning and creating such borders as material artifacts but the everyday work of living with and imagining such borders, particular in the Ferghana valley region where Uzbekistan and Kyrgyzstan meet. The effects and affects of such borders are manifold.

Religion

As Liu (2011: p. 120) notes, Islam has been privileged in studies of the region. In part, this is down to grand narratives from the Soviet period onward according it a monolithic role that more nuanced ethnographic accounts have been able to tease apart. Thus, in Massell's (1974) persuasive account of the early Soviet period, veiled women took the place of the missing proletariat, as symbolic objects of all that was oppressive,

patriarchal, and backward about Central Asia, even though veiling was limited to Uzbekistan and Tajikistan. There are, at least, three reasons for academic interest in Islam rising again from the 1990s onward: (1) there was a huge burst of building mosques (alongside Protestant missionary activity), many of which were funded by external sources; (2) the notion that allowing Islamic practice would allow the resurgence of related suppressed traditions; and (3) the apparent growth of Islam together with links to Muslim 'states of concern' via funding neatly replaced north American fears of communism with fears of militant Islam. On this point, Hetherington and Heathershaw and Megoran (2011) highlight the recurrent orientalist discourse of danger and violence in Central Asia that continues to affect and distort both policy and much scholarship.

For all the Soviets rejected Freudianism as linked to false bourgeois consciousness, there is a curious consistency in how Islamic practice is first seen as repressing gender equality and then in turn as being both repressed and a container of all other traditions similarly disparaged or outlawed during the Soviet Union. The problem with this archaeological, or layered, approach to a national consciousness, even if not so termed, is the temptation to act as though one need only scratch the surface for a particular social organization to be restored. Once again, there are several views on the relationship between contemporary and earlier forms of Islam in Central Asia, as well to other lost practices and indeed, to widen the frame, to Islamic states elsewhere.

Khalid (2007) suggests that the Soviet evisceration of religion was so effective, that after 1991 there was little sense of what Islam was, beyond a loose recognition that certain ethnic affiliations and religious confessions once had an affinity: to be Kazakh, was thus *ipso facto* to be Muslim, irrespective of practice, knowledge, or belief. The efflorescence of different ways of practicing Islam created new anxieties over what was or was not 'correct' or might be seen as extremist (McBrien, 2009) and who had authority to make such pronouncements (Waite, 2006). Arguably (McBrien and Pelkmans, 2008), there are parallels between the ideology of a competitive neoliberal market and the range of new religions on offer, echoing Ruthven (1991). Again, where some shrines had once been ignored, and thus covertly allowed a variety of practices, a new openness also brought out attempts to control and circumscribe observances (Alexander, 2004a; Kehl-Bodrogi, 2006). Similarly perhaps, since the domestic realm was not immediately in the public eye, it became an important conduit for continuing and passing on religious and other rituals and traditions (Kandiyoti and Azimova, 2004; Fathi, 2006). Clark (2009) notes that homes and domestic networks of families and friends are typically the means through which Protestant Christianity is also taking a strong hold in Almaty.

State responses to religion throw up the contradictions of nominally embracing liberalism while also trying to control the national ideology. Kazakhstan's president may be seen on television almost running from Eid celebrations one minute to attend Easter Mass the next. The lack of open religious debate in Uzbekistan on the other hand, suggests that, once again, it is in the less observed everyday arenas that a variety of religious and healing practices are to be found.

Conclusion

Many topics remain unstudied or scarcely covered. Energy and water politics seem to be largely the province of politics and international relations, with little sense of how energy and water shortages locally or giant pipelines using productive land are affecting people's everyday lives. Just as Central Asia received waves of settlers hungry for land after the emancipation of the serfs in 1861, political prisoners, volunteers for new enterprises, and deportations of entire populations so too was it subject to extreme Soviet agricultural, military, and other experiments, often with long-lasting, devastating environmental consequences. Three examples give an indication. Cotton monoculture in Tajikistan and Uzbekistan required high irrigation that drained the Aral Sea; the central steppe's thin soil was plowed up; northeast Kazakhstan was turned over to nuclear tests. The legacy of these interventions is extreme; so far, there have been few anthropological engagements with what they mean (Werner and Purvis-Roberts, 2006, 2007 are the exceptions here). Labor migration continues apace, between farm and city, between impoverished countryside and the West. Marat (2009) aside, there have been few studies of the effects of the economic crisis. Next to nothing has been written on industrial relations in these resource-rich countries (where strikes appear to be increasing) and on emerging forms of inequality within, as well as between, ethnic groups. It would be good to see the concern with the politics of performance and representation matched by the politics of resource allocation as the growing gap between rich and poor that marks neoliberal regimes also takes hold. Certainly, the increasing distance between rich and poor, urban and rural areas often outweighs ethnic affiliation.

In returning to the movement, fluidity and far-reaching imaginations that have always characterized this region, ethnography is a vital means of countering stereotypes encountered both externally and in self-exegeses – whether demonstrating transformative, traditional or hybrid, syncretic patterns of social life. If early accounts emphasized top-down nation-state building, ethnography shows the inadequacy of the nation-state concept in suggesting the lived plurality of lives in Central Asia. Fully capturing the far-flung networks of ethnic groups that variously live (often choosing to live) in diasporic conditions, in mobile trading relationships, and in their titular state has yet to happen. Equally, a move to consider Central Asia as part of global processes of accumulation by dispossession in the late twentieth and twenty-first centuries would enable a stronger sense of its commonality and specificity juxtaposed with global economies of which it is now irrevocably part.

Abstract

Ceramics, among the oldest and most significant technological innovations in the history of humankind, are ubiquitous in many archaeological contexts, and provide archaeologists with one of their main categories of empirical data. Studies of variation in ceramic production, style, and use have assisted archaeologists both in the construction of chronologies and in the interpretation of ancient societies. Four main areas of archaeological study of ceramics are reviewed: (a) the classification of pottery; (b) the use of ceramics in chronology construction and dating; (c) the characterization and sourcing of pottery; and (d) ethnoarchaeological studies of traditional pottery-making industries.

Ceramics, or pottery, are among the oldest and most significant technological innovations in the history of humankind, the first truly synthetic material. Being highly plastic and thus virtually infinite in the range of shapes and forms possible, offering ready surfaces for decoration, and being ubiquitous in many archaeological contexts, ceramic containers and artifacts have provided archaeologists with one of their main categories of empirical data. Studies of variation in ceramic production, style, and use have assisted archaeologists both in the construction of chronologies and in the interpretation of ancient societies.

Ceramics denotes objects made from clay and fired to achieve hardness, which range from low-fired terra- cottas and earthenwares (firing range 900–1200 °C), through stonewares (1200–1350 °C), to porcelains (1300–1450 °C) (Gosselain, 1992). Most archaeological analyses of ceramics are focused on earthenwares, which dominated pottery industries throughout most of prehistory. Aside from vessels and containers of all kinds, ceramic artifacts also include such important items as bricks and tiles, figurines and models, and tableware.

History of Ceramics

The earliest human experimentation with clay – including the discovery that moist clay is plastic, can be shaped, and when heated or fired will retain its shaped form – is not well documented archaeologically. Fired clay figurines are known from the Dolní Vëstonice site in Czechoslovakia, dated to 30 000 BC (Vandiver et al., 1991). In the Old World, the first ceramic vessels appear in the early Jomon culture of Japan at about 10 000 BC, and in the Near East (Anatolia) at around 8500–8000 BC. Ceramics do not appear until considerably later in the New World, where it appears that the technology was independently developed in several localities between 5500–2500 BC. In all cases, the origins of ceramic vessels appear to be closely associated with sedentary modes of life, and with storage either of agricultural products or of quantities of gathered plant foods (as in the Jomon case). There is a high degree of correlation between sedentism and pottery making, as evident in a world ethnographic sample where only two out of 46 pottery-making societies are nonsedentary (Eerkens et al., 2002).

The oldest known pottery in the world is the 'cord-marked' Jomon pottery industry of Japan, dating to 10 000 BC and associated with sedentary or semi-sedentary hunter-gatherers (Zhushchikhovskaya, 2012). Jomon pottery is highly distinctive, both with its cord or string-impressed surface decoration, and its elaborate modeled rims; vessel forms are typically high jars or beakers. Elsewhere in the Far East, pottery appears in parts of China by around 7000 BC, if not earlier. The Yangshao-Culture, centered in the Yellow River valley of northern China and dating between 4800–4200 BC, is noted for its beautifully formed earthenware jars and dishes, decorated with red-and-black painted geometric designs. In later time periods, the Chinese perfected many technical aspects of ceramic production, such as the horizontal and vertical updraft kilns, the potter's wheel, and high-fired stonewares and glazes (Kuzmin, 2006). Porcelain ceramics were innovated in China sometime around the beginning of the first millennium AD, and were widely traded throughout the Old World, and later to Europe and the Americas.

In the Near East, architectural uses of clay (e.g., for walls, floors, and roofs) are widespread by around 7500 BC, in association with the domestication of plants and animals, and the origins of sedentary village life. Pottery containers appear by 8500–8000 BC in Anatolia, and slightly later in other parts of the Near East. A variety of other clay implements and artifacts are also characteristic of early Near Eastern sites, such as clay spindle whorls and loom weights, clay sickles (with obsidian or flint blades), clay toys and models, and clay stamps and cylinder seals (Byrd, 2005). Ceramic technology was not independently developed in Europe, but rather was borrowed or diffused from the Near East, in association with the spread of agriculture and a sedentary mode of existence. In the classical world, of course, Greek black- and red-figured pottery (600–400 BC) represents a high level of technical and artistic achievement, as does slightly later Roman Arretine ware (100 BC–AD 400).

Ceramic technology in the New World arose considerably later in time, evidently as an independent development; moreover, the potter's wheel and the use of glazes never developed in the New World. The earliest known pottery in

the New World is from the Amazon basin and dates to approximately 5500 BC (Roosevelt et al., 1991; *see* South America, Archaeology of). Fiber-tempered pottery has been found in the Southeastern United States from 2500 BC (Saunders and Hays, 2006) while pottery in Pacific coastal Mesoamerica dates to approximately 2000 BC (Clark and Gosser, 1995). Among the outstanding pottery traditions of the New World, one must count the coastal Peruvian Nazca and Moche traditions (200 BC to AD 700) with their elaborated modeled anthropomorphic and zoomorphic vessels (Chatfield, 2007); the Late Classic Maya pottery which included exquisite polychrome funerary vessels; and the Pueblo pottery traditions of the southwestern United States.

Archaeological Approaches to Ceramics

Ceramics have played a central role in archaeological method and theory, for several reasons: (a) pottery has a long history, and is virtually ubiquitous in most sedentary societies; (b) pottery is nonperishable, and is often recovered in very large quantities from archaeological excavations; (c) pottery functioned both as utilitarian cooking, storage, and serving vessels for all strata of a society, as well as special purpose functions for elite ceremonial or funerary use; and, (d) as a highly plastic material, pottery displays seemingly infinite variation in composition, manufacturing method, shape, and decoration (Orton and Hughes, 2013) . These variations, moreover, were culturally conditioned, resulting in particular ceramic styles or traditions, which can be traced through time and space.

Early in the development of modern archaeology, scholars such as Flinders Petrie in Egypt, and somewhat later James Ford, Irving Rouse, and James Griffin in North America, recognized the value of ceramic studies in developing relative chronologies based on changes in ceramic style over time. Prior to the development of such absolute chronometric dating methods as radiocarbon or dendrochronology (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology), the construction of ceramic chronologies were essential to developing local and regional time frames for prehistoric cultures.

With the rise of absolute dating methods in the second half of the twentieth century, archaeological studies of ceramics have shifted somewhat, with less emphasis on classification, seriation, and chronology construction, in favor of new approaches. These include detailed physical and chemical studies of ceramic composition and of production techniques and sequences, which inform archaeologists about the technology of ceramic production and use, and about the distribution and movement of ceramic vessels during their life spans (Sharer and Ashmore, 2003). Such information in turn is useful to archaeologists who are attempting to understand prehistoric economic and sociopolitical organization.

Classification of Ceramics

As perhaps the most plastic of all material culture media known in antiquity, ceramics exhibit enormous variation – in fabric, methods of production, shape, decoration, and function – offering tremendous advantages as well as challenges to the archaeologist. In order to bring some order to this variability, archaeologists must classify pottery into sets of like objects. The aims and methods of ceramic classification, however, depend greatly upon the particular archaeological approach. For example, a classification which is aimed at the discovery of historical types, those which show meaningful variation over time, will most likely emphasize different aspects of variation from a classification designed to exhibit key differences in manufacturing process. The literature on archaeological classification of ceramics is vast, but useful overviews may be found in Shepard (1965), Rice (1987), and Sinopoli (1991).

Ceramic classifications may be based on a number of different kinds of variables, the most common being technological dimensions, vessel shape, and decoration (Orton and Hughes, 2013). Classifications based on technological dimensions are especially useful when the aim is to understand production processes, although such dimensions may also be useful in the definition of historical types. Major technological dimensions include raw materials (especially clay and nonplastic inclusions such as mineral temper), methods of vessel forming (such as coiling or slab building, and the use of the potter's wheel), secondary treatments (such as the application of slips or glazes), and methods of firing (open air firing, use of kilns). Vessel shape may be classified formally according to various systems, such as that developed by Shepard (1965), which distinguishes between restricted and unrestricted vessels, and further between composite and inflected shapes. Vessel shape, naturally, is closely linked with vessel function. The third major category of variation used in ceramic classification is that of decoration and surface treatment. Possible surface treatments include slipped, glazed, burnished, polished, paddle-impressed, and smoothed. Decorations may be applied by painting, stamping, incising, carving, or other methods, such as three-dimension appliqué or relief. Designs used in decorations typically consist of individual design elements, which are systematically organized into motifs and larger decorative panels, and generally follow culturally-determined rules. The classification and analysis of such design systems may be based on individual motif catalogs and set of design rules (e.g., Mead et al., 1975), or on analysis of underlying principles of symmetry (e.g., Washburn, 1977).

Methods of ceramic classification also vary. Pottery producers have their own indigenous or folk classification systems, which have been the subject of considerable ethnoarchaeological study (see Section Ethnoarchaeology and Ceramics below). Formal archaeological procedures for classifying pottery include the well-developed 'type-variety' system, first applied in North America and later extended to Mesoamerica. This system uses a 'binomial' nomenclature, in which a geographic name is combined with some specific technological descriptor (e.g., 'Barton incised'). Classification schemes range from simple paradigmatic classifications, to complex, hierarchical taxonomies. An alternative approach, much favored in the 1960s and 1970s, is quantitative or phenetic classification, in which 'types' are generated by a computer, following certain mathematical algorithms operating upon a number of qualitative and/or quantitative parameters. The prime example of such a numerical taxonomy of ceramics is that of Clarke (1970) for the Bell Beaker pottery

complex of Great Britain. Scholars in have revisited the use of quantitative methods in the 21st century as computers have become increasingly powerful and capable of analyzing very large quantities of data (Smith et al., 2014).

Ceramics and Chronology

The emphasis accorded ceramic studies by archaeologists reflects the importance of using ceramic change as a means for constructing cultural chronologies. In the late nineteenth century, pioneering Egyptologist Flinders Petrie recognized that pottery vessels which had been placed in tomb groups as funerary objects showed subtle but continuous stylistic changes over time (Stevenson, 2014). Petrie arranged representative vessels in an inferred chronological sequence, resulting in the first seriation of pottery.

The methods of seriation were greatly refined by American archaeologists, such as Irving Rouse and James A. Ford (1962), working with ceramic assemblages from various New World localities, including the Mississippi Valley region, and the Viru Valley of Peru (O'Brien et al., 2000). Their work generated much debate concerning the methods of ceramic classification and the reality of ceramic 'types.' The fundamental principle of seriation was to define a set of historical types which displayed gradual temporal changes, with a particular type arising at some point in time, gradually increasing in popularity (hence reflected by increased frequency in archaeological assemblages), and later decreasing until the type disappeared from the archaeological record (Peeples and Schachner, 2014). When the frequencies of such historical types were plotted as percentage diagrams, they displayed a characteristic frequency distribution resembling the plan of a battleship, and hence were known as 'battleship curves.'

The great advantage of seriation was that it permitted the construction of cultural chronologies independent of any 'absolute' method of direct dating. Surface collections of potsherds from sites of unknown age could be tabulated according to the frequency of key ceramic types, and then chronologically ordered by arranging the frequency distributions to form 'battleship curves.' Moreover, local ceramic chronologies could be linked together using trade pottery which occurred in more than one region, or by tracing the diffusion of particular stylistic traits. With the invention of radiocarbon dating and other methods of 'absolute' dating in the later half of the twentieth century, the importance of seriation has declined, although it is still important as a cross-check on radiocarbon-based chronologies (Peeples and Schachner, 2014).

Pottery may also be directly dated, either by radiocarbon dating of organic inclusions within the ceramic fabric (i.e., dung or chaff included as temper), or by thermoluminescence (TL) dating. TL dating is based on the fact that when clay and other geological inclusions in pottery are fired at temperatures of 500 °C or higher, electrons which had been 'trapped' in the crystal lattice structure are freed, emitting light or thermoluminescence (Raju et al., 2014). Following the firing process, new trapped electrons gradually accumulate in the crystalline imperfections of the pottery, as a natural consequence of radioactive decay. If ancient pottery is then reheated in the laboratory up to 500 °C, and the emitted light is measured and plotted as a 'glow curve' of intensity vs. temperature, the age of the specimen can be calculated, since the intensity of light emitted will be proportional to age. There are, of course, many possible complications deriving from the geological composition of the fabric, and from post-depositional conditions affecting the pottery. As a result, TL dating is less widely used than the radiocarbon method.

Compositional Studies

Within many ancient societies, pottery was produced by specialists who then traded, exchanged, or sold their wares to other nonpottery producing sectors of society, and/or to other villages or geographic localities. Moreover, pottery was frequently traded or exchanged over considerable distances. Tracing the production, distribution, and specialized use of pottery in ancient societies requires that the archaeologist be able to characterize the unique composition of a particular ceramic product, typically a mix of clay and other nonplastic inclusions (including purposefully added 'temper.') A key phase in archaeological pottery analysis is thus ceramic characterization (Bishop et al., 1982). Characterization may also include efforts at sourcing, in which the materials that make up a particular ceramic ware are traced to their geographic points of origin, such as local clay quarries or sources of sand used as temper.

A wide range of mineralogical and geo-chemical techniques have been applied to ceramic compositional analysis, whether for characterization or sourcing. Petrographic analysis of the nonplastic inclusions within a ceramic fabric, in which the specific mineral grains are identified by examining a thin section of the pottery under a polarizing microscope, is a widely used technique (Baxter et al., 2008). X-ray diffraction, which identifies minerals by their crystalline structures, is another frequently applied method for the characterization of pottery on the basis on the temper or non-plastic inclusions. Other techniques which have been applied more recently include optical emission spectroscopy, X-ray fluorescence spectroscopy, atomic absorption spectroscopy, neutron activation analysis, proton-induced X-ray emission, Mössbauer spectroscopy, electronic microprobe analysis, and inductively-coupled plasma analysis (see Rice, 1987 for a review of these and other methods; Pillay et al., 2000).

Ethnoarchaeology and Ceramics

Given the importance of ceramics in archaeology, it is not surprising that archaeologists have turned to traditional pottery-making societies to learn more about potential variability in ceramic production, distribution, use, and discard. The study of contemporary peoples, using ethnographic methods of participant-observation, in order to gain knowledge of material culture variability which is potentially applicable to the interpretation of archaeological assemblages, is called ethnoarchaeology (*see* Ethnoarchaeology). Ceramic ethnoarchaeology (Kramer, 1985; Stark, 2003) is perhaps one of them most important subfields within this topic (Longacre, 1991).

Because archaeologists had long been concerned with the classification of ceramics, a number of ethnoarchaeological studies have focused on the ways in which traditional potters

classified or categorized their own products. Indigenous potters typically pay little attention to the technological attributes often accorded emphasis by archaeologists (such as details of temper, paste, surface treatment, or decoration), but rather emphasize general function in their folk classifications. Thus, among the Kalinga of the Philippines, pottery vessels are distinguished by whether they are intended for cooking rice or for cooking vegetables and meat, and by their sizes (Beck, 2006; Longacre, 1981). The Fulani of Cameroon (David and Hennig, 1972) lexically discriminate among five size classes of jars, with secondary classification based on their intended contents.

Other ethnoarchaeological studies of pottery have focused on aspects of ceramic production, including the social role or status of potters in their societies, on ceramic distribution, on the use of vessels, their life spans, and on their breakage and discard rates (see Kramer, 1985 for a general review). Such studies have aided archaeologists in their interpretations of ancient ceramics by revealing the complex linkages between behavior and material culture, demonstrating that strictly utilitarian explanations for archaeological phenomena are not always preferable, and by showing that multiple lines of evidence may help to discriminate between alternative explanations (Stark, 2003).

Abstract

In the nineteenth century, researchers reached a consensus on the basis of animal ablation experiments that damage to the cerebellum leads to motor disorders but does not affect its sensory or cognitive functions. This model has been so influential that for over 100 years, the cerebellum has been considered to be strictly involved in motor control, whereas cerebellar function in cognition has been hotly debated. The current consensus is centered around the belief that the cerebellum intervenes in many domains, from motor to emotion and from sensory processing to learning. This article discusses the cognitive functions of the cerebellum. Examples of cerebellar involvement in various higher-cognition functions will be provided, and theories on the specificity of the cerebellar contribution to cognition will be advanced.

History

In the early twentieth century, Stewart and Holmes (Holmes, 1917) reported that cerebellar lesions due to tumors or gunshots effect motor deficits in humans, such as decreased muscle tone, impaired coordination of movements, and deficits in the regulation of gait and posture. Holmes's studies were influential and introduced the cerebellum as a purely motor structure. Nevertheless, even in the 1800s, intellectual, psychiatric, and social–emotional dysfunctions were observed in patients with cerebellar degeneration and agenesis (see reviews by Macchi and Bentivoglio, 1987; Schmahmann, 1991).

The concept of cerebellar function outside of the motor domain, focusing primarily on autonomic and limbic functions, was renewed by Snider in the 1950s (Snider, 1950). But only in the 1980s has research on cerebellar function in cognition gained momentum (Leiner et al., 1986; Schmahmann, 1991).

General Principles of the Anatomophysiological Cerebro-Cerebellar Interactions

The organization of the cerebello-thalamo-cortico-ponto-cerebellar loop has been examined extensively in monkeys (Schmahmann and Pandya, 1997; Middleton and Strick, 2000). According to these findings, cerebello-cortical circuits are organized in close parallel loops. Each cortical area that sends elements to the cerebellum via the pontine nuclei is also the recipient of a returning loop by the cerebello-thalamic bundle. Cerebellar efferents originate from deep cerebellar nuclei and are organized into segregated channels that reach specific cortical zones by a disynaptic pathway through the thalamus. Similarly, the cortico-ponto-cerebellar stream presents segregated channels (Ramnani, 2006).

The introduction of electrical and magnetic stimulation of brain structures through the scalp has made the neurophysiological study of neuronal circuitries in humans possible on a large scale; this technique has also been used to address the nature of cerebro-cerebellar interactions neurophysiologically. Thus, by modifying the function of cerebellar circuits through noninvasive brain stimulation techniques, such as transcranial magnetic stimulation and transcranial direct current stimulation, it is possible to analyze the effects of cerebellar modulation over the cerebral cortex in humans directly (Bijsterbosch et al., 2012).

It is generally accepted that cerebellar input has a facilitating effect on the contralateral cerebral cortex – chronic cerebellar damage reduces the excitability of the contralateral motor cortex (Di Lazzaro et al., 1995). Conversely, disparate effects on the cerebral cortex after cerebellar stimulation have been reported (Ferrucci et al., 2012; Lu et al., 2012). By varying the parameters of cerebellar stimulation, it is possible to modify the ultimate effect on the cerebral cortex (Hamada et al., 2012).

Early neurophysiological studies on cerebro-cerebellar interactions focused on sensory motor processing (Bower and Parsons, 2003), and recent reports have determined the function of the cerebellum in allowing sensory information to modulate motor cortex excitability (Taib and Manto, 2009). In the sensorimotor domain, clinical and experimental data converge, indicating that the cerebellum links the crosstalk between the somatosensory and motor cortices. How does this mechanism work? Are somatosensory influences on the motor cortex mediated by cerebello-M1 circuits, or does the cerebellar output affect the somatosensory cortex directly?

Hints to the answers can be found in observations in humans with focal lesions of the cerebellum. Isolated cerebellar lesions affect S1 intracortical processing of simple somatosensory stimuli, as shown in subjects with unilateral focal cerebellar lesions, in which early somatosensory evoked potentials (SEPs) of the primari somatosensory (SI) cortex that is contralateral to the lesioned cerebellum are altered (Restuccia et al., 2001). In particular, the amplitude of the frontal N24 and parietal P24 SEP components and the strength of the corresponding dipolar sources are significantly lower in the hemisphere that lacks the cerebellar input compared with the contralateral side.

The finding that cerebellar damage influences the early components of SI processing supports the existence of a direct influence of the cerebellum over S1- rather than an undirected one through M1. This datum is consistent with findings in monkeys of different segregated cerebro-cerebellar loops targeting, beside the motor areas, also the parietal lobe

(Clower et al., 2001). The function of such an early influence can be understood, considering the predictive properties of cerebellar processing (Bastian, 2006). In this framework, the early influence might be to gauge cerebellar capacity to alert the cortex before the arrival of a predicted incoming volley (Tesche and Karhu, 2000; Ivry, 2000).

How can the cerebellum predict the next event in the cerebral cortex? The cerebellar capacity to process sequences of events and, in particular, detect predictable ones (Molinari et al., 2009) by sequencing has been observed in the motor (Manto et al., 2012), somatosensory (Restuccia et al., 2007), temporal (Moberget et al., 2008), and cognitive domains (Leggio et al., 2008). These studies reported sequencing and event prediction impairments that were associated with cerebellar damage. This significance of sequencing in defining cerebellar function in various domains is a novel support for the hypothesis of sequencing as the basic cerebellar mode of operation (Braitenberg et al., 1997; Molinari et al., 2008).

Cerebellar Cognitive Functions

In 1998, Schmahmann and Sherman (Schmahmann and Sherman, 1998) described 'cerebellar cognitive affective syndrome,' reporting impairments in executive functions, disturbances in spatial cognition, language deficits, and personality changes in subjects with cerebellar pathologies. This early report was confirmed and expanded by several groups. The current list of cognitive functions that are impaired in association with cerebellar malfunctioning includes executive functions (Kim et al., 1994; Gottwald et al., 2004; Bellebaum and Daum, 2007), visuospatial functions (Neau et al., 2000; Molinari et al., 2004), working memory (Silveri et al., 1998; Chiricozzi et al., 2008; Marvel and Desmond, 2010), verbal memory (Grasby et al., 1993), linguistic processing (Petersen et al., 1988), verbal fluency (Leggio et al., 2000; Peterburs et al., 2010), procedural learning (Molinari et al., 1997; Shin and Ivry, 2003), attention (Allen et al., 1997; Gottwald et al., 2004), sequencing (Leggio et al., 2008; Moberget et al., 2008), and emotion (Schmahmann and Sherman, 1998; Turner et al., 2007).

Consistent with lesion studies, there are functional magnetic resonance imaging (fMRI) data on healthy subjects on cerebellar activation in several cognitive functions, from which a consensus has been forming on the topographical distribution of various cognitive domains in the posterior lobe of the cerebellum, independent of sensorimotor somatotopy (Stoodley et al., 2012). More recent brain stimulation studies that have targeted cerebellar structures are providing additional evidence of cerebellar cognitive processing (Ferrucci et al., 2008, 2012; Pope and Miall, 2012). An exhaustive list of reports that implicate cerebellar involvement in various domains is beyond our objective; thus, we will focus on verbal working memory (vWM) and mental functions with regard to increasing our understanding of cerebellar function in cognition.

Cerebellum and vWM

The contribution of the cerebellum to vWM has been examined by several groups, which have generated notable results that have enhanced our comprehension of the cerebellar contribution to cognition. After early fMRI findings of cerebellar activation during vWM tasks (Desmond and Fiez, 1998; Thomas et al., 1999), Silveri et al., first demonstrated vWM dysfunction in a cerebellar patient (Silveri et al., 1998).

Since then, many groups have noted cerebellum-related vWM impairments that generally refer to the highly influential model that was proposed by Baddeley (Baddeley, 2003) to support their findings. According to this model, the phonological loop is the system that processes language-related information. This loop comprises two distinct components: The articulatory rehearsal, located in Broca's, the premotor, and supplementary motor cortical areas, and the phonological store, located in the parietal lobe (Keren et al., 2012).

The cerebellum has only recently been added to the list of neural structures that are involved in vWM, but its contribution remains unknown. Due to the clinical characteristics of the deficit, the first report on vWM impairment from cerebellar damage concluded that the cerebellar contribution lay in the articulatory control process rather than the phonological storage component of vWM (Silveri et al., 1998). Later, in various subjects with cerebellar damage, Justus and colleagues reported vWM impairments to the phonological output buffer or phonological analyses (Ravizza et al., 2006). A recent single-case study reported cerebellum-related damage to the phonological short-term store (Chiricozzi et al., 2008). Thus, data from lesion studies indicate that the cerebellum acts on many levels of vWM processing.

The complexity of the cerebellar contribution to vWM has been confirmed by neuroimaging studies, which have noted that various cerebellar lobules are active when different vWM components are called into action (Cooper et al., 2012). In particular, Desmond and colleagues differentiated at least two segregated cerebro-cerebellar loops that were active during vWM tasks in a series of fMRI studies. According to their findings, the superior cerebellum is a part of a cerebro-cerebellar motor circuit that includes Broca's area and the supplementary motor area, which creates motor-related articulatory trajectory paths (orthographic to phonological translation). Conversely, the inferior cerebellum is part of a circuit that involves BA40 and supports the maintenance of information in the phonological store (Marvel and Desmond, 2010).

The presence of various function-specific cerebro-cerebellar loops that support vWM has also been confirmed by morphometric studies in subjects with spinocerebellar ataxia type 6 (SCA6) cerebellar degeneration. In a comparison of vWM performance and cerebellar cortex volume, a critical relationship between vWM and gray matter density was demonstrated in the superior (bilateral lobules VI and crus I of lobule VII) and inferior (bilateral lobules VIIIa and VIIIb, and right lobule IX) sections of the cerebellum. Notably, in these areas, distinct cerebellar regions subserve various vWM functions. Specifically, the areas that are devoted to the phonological loop can be differentiated from those that support the central executive components of Baddeley's model of vWM (Cooper et al., 2012).

Considering that Baddeley's cognitive modules lie in disparate areas of the cerebral cortex (Smith and Jonides, 1998) and based on the modular organization of cerebello-cortical

connections, the clinical manifestations of cerebellar damage on vWM might depend on the region of the cerebellum and the associated cerebro-cerebellar connection that is damaged (Marvel and Desmond, 2010).

Thus, on examination of a specific cognitive function, such as vWM, the function of the cerebellum appears to be difficult to identify. As in the early approaches of studying cerebellar function in cognition, nearly all abilities require cerebellar contribution. Nevertheless, due to the unitary nature of cerebellar anatomical modules, the basic operational mode in various domains should be the same.

The Cerebellum and Mental Function

The study of mental functions with regard to the cerebellum is an area of significant interest. As discussed, since the early definition of Cerebellar Cognitive Affective Syndrome (Schmahmann and Sherman, 1998), mood disorders, personality changes, and inappropriate behaviors have been linked to cerebellar damage. Conversely, the cerebellum has been considered to mediate the pathogenesis of several neuropsychiatric disorders – schizophrenia, depression, autism, and dyslexia. Further, among degenerative cerebellar disease, the rate of psychiatric diseases is high (Leroi et al., 2002). How cerebellar processing intervenes in affecting mental health is unknown, but the answer might be obtained by analyzing cerebellar involvement in the pathogenesis of schizophrenia and autism.

Schizophrenia is defined as a mental disorder that is characterized by a dissociation between internal representations and external reality. Considering the classical cerebellar function as a comparator between functional states (Ito, 2005), it is conceivable that internal vs external reality representations involve the cerebellum. Moreover, it is notable that in reporting cognitive defects in subjects with cerebellar damage, terms that are characteristic of psychosis, such as cognitive dysmetria and dysmetria of thought, have been used (Schmahmann, 2010). Several years ago, a cerebellar theory of schizophrenia was even advanced (Picard et al., 2008).

Further, as cerebellar patients, schizophrenic patients present with deficits in perceptual and motor processing, attentional skills, vigilance, vWM, and verbal fluency (Synofzik et al., 2010; Tedesco et al., 2011). Notably, impairments in predictive abilities have been reported, at least for the sensorimotor domain, in schizophrenia (Synofzik et al., 2010) and after cerebellar damage (Bastian, 2006).

Neurophysiologically, it is possible to evaluate the capacity to recognize unexpected changes in incoming volleys of sensory data using the MisMatch Negativity (MMN) paradigm. MMN is a brain event-related potential that reflects the capacity of the human brain to detect deviance in the environment preattentively. MMN is considered as an effective measure of the processing of preattentive information by change detection. MMN is thus recorded as a negative event-related potential (ERP) component that is elicited by deviant stimulus – i.e., changes in the frequency, duration, intensity, or location of a standard stimulus. The MMN is believed to be the outcome of a comparison process that is commonly elicited when an incoming stimulus differs from the memory of repetitive ones (standards) that occurred in the recent past. This comparison is altered for acoustic stimuli in schizophrenia (Zhou et al., 2013) and in cerebellar patients for acoustic (Moberget et al., 2008) and somatosensory stimuli (Restuccia et al., 2007).

For both pathologies, the core alteration in associated behavioral disturbances has been linked to the inability to detect changes in sensory patterns. The inability to predict sensory patterns correlates with the difficulties of schizophrenia in recognizing an action on the basis of subject intent (D'Angelo and Casali, 2013). Somehow, in parallel, cerebellar patients encounter difficulties in recognizing actions and behaviors (Leggio et al., 2008).

Autism is a developmental disorder in which cerebellar damage or malfunction is often considered among possible pathogenic mechanisms (Fatemi et al., 2012). The strongest link between the cerebellum and autism derives from the coexistence of cerebellar-like motor symptoms that affect basic motor control, postural stability, and skilled gestures and abnormal patterns of motor learning in most persons with autism (Nebel et al., 2012), as well as the presence of abnormalities in cerebellar structures (Abell et al., 1999).

Similarities between autism and cerebellar symptoms are present with regard to cognitive deficits. Individuals with autism have impairments in executive function, memory, and language – all domains that are altered in subjects with cerebellar damage (Tedesco et al., 2011). Notably, the core neurobehavioral features of autism – impaired social interaction, isolated areas of interest, and an insistence on sameness – can be related to impairments in cerebellar processing. Based on neurophysiological findings, it has been suggested that the cerebellum is central to the analysis of sequential events in the behavioral domain (Molinari et al., 2008).

The capacity to adapt to a given context behaviorally depends on the ability to recognize the perceived pattern. Only if the perceived context is recognized as pertinent to previous knowledge it is possible to develop the correct behavior. For example, if one is presented to the Japanese emperor for the first time, it is highly likely that he will not know the proper decorum. Yet, an experienced courtier of the Japanese Imperial palace will immediately adapt his behavior, even to small changes in the attitudes of others in the room.

Cerebellar damage will reduce one's capacity to detect a pattern, thus impeding the recognition of a previously encountered context and preventing the appropriate behavior from being assumed. Thus, it is understandable how cerebellum-related difficulties in recognizing a behavioral pattern will impair social interactions and the capacity to adapt to new areas, and favoring the tendency to repeat a fixed behavior.

The Basic Operational Mode of the Cerebellum in Cognition

Despite the increase in data on the cerebellum in cognitive and behavioral functions, the precise definition of cerebellar processing has not been determined. It is generally acknowledged that due the regularity and substantial uniformity of cerebellar modules, the same basic functions should be exerted by the cerebellum in the motor, cognitive, and affection-related domains (Ito, 2008). In particular, based on studies in the

motor domain, the hypothesis that cerebellar processing allows event prediction of subsequent states (Bo et al., 2008) has been expanded to the cognitive domain.

Cerebellar sequencing has been suggested to be at the core of cerebellar capacities in predicting future states in the sensorimotor, cognitive and behavioral domains (Braitenberg et al., 1997; Molinari et al., 2009; D'Angelo and Casali, 2013). In a recent study of more than 200 cerebellar patients, over a wide range of cognitive domains, sequencing was the most affected domain, independent of the nature (degenerative or focal) or anatomical location of the lesion (Tedesco et al., 2011).

Evidence of the significance of cerebellar processing in behavioral predictions and in pathogenesis neuropsychiatric disorders, such as autism and schizophrenia, has been reported in the studies above. Neuroimaging, neurophysiological, and clinical data are consistent in suggesting that the cerebellum, in parallel to proposals in the somatomotor domain (Bo et al., 2008), is a predictive device in cognitive processes, including vWM (Ben Yehudah et al., 2007).

Notably, disparate lines of research suggest that the detection and coordination of spatiotemporal patterns – such as sequencing – constitute the common basic principle of cerebellar neuronal operation in all functional domains.

The model of the cerebellum as the key element that allows smooth, organized spatiotemporal muscular patterns dates back to Holmes (Holmes, 1917). Based solely on anatomical evidence of the cerebellar circuits, sequencing has been suggested to be the chief result of cerebellar neuronal processing. Specifically, the cerebellar cortex allows to detect sequences of incoming activity and generate precise output sequences (Braitenberg et al., 1997). As regards cognition, the same basic processing of sequencing and the complexity of the cortico-cerebellar loops allows the cerebellum to support cortical function by detecting and coordinating spatiotemporal cortical activity patterns at the level of spike activity (Fatemi et al., 2012) or functional modules (Molinari et al., 2008).

Abstract

Forming the outer layer of the forebrain, the cerebral cortex is the largest body of gray matter in the brain. It is made up of three distinct parts, namely the isocortex, which is phylogenetically the youngest part of the brain and is therefore often referred to as the neocortex, and the ancestrally older archi- and paleocortices, of which the hippocampus is the most prominent example. The cerebral cortices are highly versatile in their function and exhibit great synaptic plasticity and change and therefore have the capacity, inter alia, for storage of vast amounts of information.

The cerebral cortex is the outer mantle (pallium) of the forebrain (telencephalon or cerebrum). It is not only the largest body of gray matter in the primate brain but also the most versatile regarding its function. Although the amount of research into cortical function has drastically increased in humans with the invention of newer neuroimaging techniques (like functional magnetic resonance imaging, fMRI), it can still be considered the greatest enigma of the nervous system. On the one hand, the immense network of fibers connecting different cortical areas, both directly and via the dorsal thalamus (see below) combined with the participation of the cortex in almost all higher cognitive functions suggest to some that it may be considered the higher-order driving force behind most brain functions. On the other hand, lesion studies, case-reports from, e.g., stroke patients or findings regarding the tremendous capacity for neural plasticity and change lead others to view upon the cerebral cortex (especially the neocortical areas; q.v., next paragraph) as the equivalent of the hard drive in a computer, rather than its central processing unit.

In general, the participation of specific cortical regions in certain tasks is interpreted differently by members of the neuroscientific world: While locationists propose that abstract mental or brain functions are attributable to discrete cortical areas, connectionists assume that the interplay of various brain regions actually represents the neural basis of brain function.

Although, to use a common idiom, the jury is still out on this question, evidence exists supporting all of the aforementioned hypotheses. It is therefore helpful to draw a distinction between those areas of the cerebral cortex that are phylogenetically older – the so-called (greater) limbic system – and those relatively young in primate evolution and, in part, unique and emergent in *Homo sapiens*.

The cerebral cortex is commonly divided according to its phylogenetic age into the younger neocortex or neopallium and the ancestrally older archi- and paleocortices. Another distinction – based on cytoarchitectonic lamination – differentiates a six-layered isocortex from a three-layered allocortex, whereby the isocortex is mostly equivalent to the neocortex and the allocortex to the archi- and paleocortices (Figure 1).

Apically, the outer layers of the cerebral cortex are surrounded by a fine glial membrane, the superficial limiting glial membrane, which in turn borders onto the microscopic subpial space. Inwards, the cerebral cortex transits into the telencephalic white matter, which encompasses the cerebral nuclei (i.e., the caudate nucleus, putamen, claustrum, amygdala, and the innominate substance of the basal forebrain including the nucleus basalis of Meynert).

Figure 2 Cerebral cortical lobes. Paulsen and Waschke. Sobotta Atlas der Anatomie des Menschen, 23rd ed. ISBN-10: 3437440705 ISBN-13: 978-3437440700; image 12.34.

The cerebral cortex is further divided into lobes, whereby the frontal, parietal, occipital and temporal lobes as well as the insula are mostly isocortical, while the – somewhat inconsistently defined – limbic lobe is made up primarily of allocortical areas. Due to the large growth of the brain in higher-mammalian phylogeny, the cerebral cortex is gyrated in many species, meaning that its surface is heavily folded into gyri, which are separated by sulci. The largest of the sulci are the lateral sulcus, separating the temporal from the frontal and parietal lobes, the central sulcus between the frontal and parietal lobes and the parietooccipital sulcus. Both cerebral hemispheres are separated by the large longitudinal fissure and connected through several commissures, the largest thereof being the corpus callosum (Figure 2).

Ontogeny and Phylogeny of the Human Cerebral Cortex

The entire forebrain develops from the most rostral of the primary brain vesicles, the prosencephalic vesicle. It forms from the neural tube around the fourth week of gestation. Around the fifth week of gestation it has further divided into the diencephalic and telecencephalic vesicles, whereby the latter gives rise to two distinct hemispheral anlages the subventricular zone, combined by a median mass known as the telencephalon impar, or the median telencephalon (Figure 3).

Initially, the cerebral hemispheres mainly increase in size, while at the end of the fifth month usually gyration starts. It is important to notice that gyration (and neural ontogeny as a whole) does not end with but continues after birth and, to a certain extent, throughout any individual's life (Figure 4).

Neuronal progenitor cells of the cerebral cortex develop, divide, and differentiate near the center of the hemispheral anlages (the subventricular zone) and then migrate in a centrifugal fashion, thereby forming the distinct layers of the cerebral cortex.

Although the human brain is by far the largest in all primate species, size and gyration are not the ultimate determinants of higher-order functions. Comparing the brain of an average human being with that of, e.g., a cetacean, one finds the brain of the latter both larger and more gyrated. The major difference, however, lies in the thickness of the cerebral cortex and the density of neurons therein (Figure 5). Primate brains have approximately double the number of nerve cells in comparison with the brains of equally sized insectivores (Rapoport, 1990). There actually appears to be a trend in hominin evolution toward a reduction in total brain size (as indicated by cranial capacities) with a growing density of neurons; i.e., Neanderthals probably had similarly sized if not slightly larger brains than modern humans; with, however, less higher-order cognitive capacities.

Of all primates, humans may have the largest brains in total, but this increase in brain volume is by no means proportional but rather specific to the emergence of higher-order cognitive and motor functions. Comparing regions of the brain belonging to, e.g., the visual or olfactory systems, humans actually have considerably less neurons than other non-hominid primates (Rapoport, 1990). Those regions having undergone the most drastic growth in human evolution can be grouped into two major systems, namely the motor system as well as large parts of the cerebral cortex, the amygdala and hippocampal formation, which may be viewed upon as the cognitive or association system (Rapoport, 1990) (Table 1).

Figure 3 Early ontogeny of the human brain. McKinley and O'Loughlin. Human Anatomy, second ed. ISBN-10: 0077361369 ISBN-13: 978-0077361365; figure 15.2.

While the rapid growth of the brain's motor system may initially appear surprising, it has to be stressed that *H. sapiens* is the only extant primate-species to have developed exclusively bipedal locomotion, thereby necessitating a tremendous increase in neuronal control of the locomotor system. Of the cognitive or association system, two important areas need to be highlighted: the first is the cerebral cortex in general and the frontal lobe in particular. Humans are the only species in which the frontal lobe is larger – and considerably so at that – than the other neocortical lobes and extends above the eye-socket (i.e., the orbitofrontal cortex). This is due to the fact that the frontal lobe is involved in motor control and movement initiation, which actually forms the basis of all higher-order human functions, including speech, thinking, imagination and – as suggested by some authors – even empathy and theory-of-mind (e.g., Guillot et al., 2012).

The second mentionable region of the human forebrain to have undergone rapid and unique evolution in humans is the nucleus basalis of Meynert. It innervates almost the entire neocortex – using the neurotransmitter acetylcholine – in a manner only found in humans and is believed to represent the basis of drive and unspecific motivation: *The activity of the newly evolved nucleus basalis stimulates humans, starting at birth, to continuously explorative activity in the social and material world. This special functional construction of the human brain is responsible for all playing activities and trials of children, leading up to social, cultural and technical creativity of adults.* (Duncker, 2005: 20) (**Figure 6**).

Cortical Lobes and Hemispheres – Interconnectivity and Lateralization

As mentioned in the introductory paragraph, the cerebral cortex is divided into two hemispheres, which are each comprised of five lobes. Each of these lobes is related to a specific function (or modality) and possesses a cortical field, which directly

Figure 4 Development of the human cerebral cortex. Paxinos and Mai. The Human Nervous System, second ed. ISBN: 978-0-12-547626-3. http://www.sciencedirect.com/science/book/9780125476263; figure 3.1.

interacts with subcortical areas. These fields are called primary fields and border on secondary and tertiary fields, which connect with the primary and other cortical fields but not directly with other brain regions. The modalities associated with the frontal, parietal, occipital and temporal lobe as well as the insula are motor control, somatosensibility, vision, hearing, and viscerosensibility, respectively. Cortical fields not clearly attributable to any specific modality but involved in the integration of different modalities or the storage of memory are referred to as association areas.

Table 1 Overview of the brain areas having undergone massive evolution in human phylogeny

Brain region	*PI*[a] *humans*	*Division with maximal progression during primate evolution*
System I: Telencephalic regions, including amygdala and hippocampal formation		
Neocortex	156	Association areas, including: – prefrontal cortex – visual association – Broca's speech area (44 and 45, Brodmann) – inferior parietal lobule (39 and 40, Brodmann) – Brodmann area 37 (part of Wernicke's speech area)
Corpus callosum	↑	
Amygdaloid complex	3.9	Corticobasolateral group subiculum, CA1, dentate gyrus
Hippocampal formation	4.2	
Entorhinal cortex	5.5	
Septum	4.0	
Nucleus basalis of meynert	↑	
System II: Segregated circuits involving basal ganglia and thalamus		
Basal ganglia	16.4	Internal segment, globus pallidus
Thalamus	↑	pulvinar, dorsomedial nucleus
Substantia nigra	16	pars compacta
Cerebellar and mesencephalic-midbrain catecholaminergic nuclei		
Cerebellar nuclei	?	Dentate nucleus
Red nucleus	↑	Parvocellular division
Raphe nucleus	?	
Locus coeruleus	?	
Ventral tegmental area	?	
Retrorubral nucleus	?	

↑: PI > 1 but value not known in humans; ?: PI not reported.
[a]Progression index in *H. sapiens* (ratio of weight of human brain to weight of brain in primitive notional insectivore of equivalent body weight).

Figure 6 Schematic representation of the proposed organization of cholinergic projections of the basal forebrain in the human brain. 1. Medial septal nucleus; 2. nucleus of the diagonal band of Broca; 3. hippocampus; 4. nucleus basalis of Meynert; 5. external capsule; 6. fornix; and 7. cingulate bundle. Fadda, F., Rossetti, Z.L., 1998. Chronic Ethanol Consumption: From Neuroadaptation to Neurodegeneration. Progress in Neurobiology 56, 385–431.

The primary field of the frontal lobe is the precentral gyrus and is separated from the primary field of the parietal lobe – the postcentral gyrus – by the large central sulcus. The precentral gyrus projects directly to interneurons of the anterior horn of the spinal cord (also called the ventral horn), thereby giving collaterals to the parvocellular and magnocellular parts of the red nucleus in the midbrain. The parvocellular red nucleus sends these motor collaterals via the central tegmental tract to the superior olivary nucleus for integration in the cerebellum (Guillain–Mollaret triangle), while the magnocellular red nucleus comprises the starting point of the rubrospinal motor tract. A small number of exceptionally large pyramidal neurons of the precentral gyrus (Betz giant cells) project directly to those alpha-motoneurons in the spinal cord which innervate the small muscles of the hand.

The postcentral gyrus receives input from somatosensory thalamic nuclei via the corona radiata. These projections form the extensions of the ascending spinal and the trigeminal lemniscal tracts and convey protopathic (e.g., coarse touch, temperature and pain) and epicritic (gentle touch) information from the somatic areas of the body. Proprioceptive information from the locomotor apparatus project to the somatosensory thalamus indirectly via the superior peduncle of the cerebellum (brachium conjunctivum).

The primary field of the occipital lobe – the striate area – represents the termination field of the optic tract. Photoceptors in the retina relay information via the optic chiasm to the lateral geniculate body of the thalamus, which in turn projects to the striate area via an extensive fiber bundle within the corona radiata, referred to as the optical radiation.

The inner aspect of the temporal lobe, directly opposite the insular cortex, is comprised of three large gyri, the transverse temporal gyri of Heschl. These form the primary auditory field and receive their input from the medial geniculate body of the thalamus via the acoustic radiation within the corona radiata, thereby comprising the termination area of the auditory tracts.

The insular cortex receives viscerosensory information from various regions of the brainstem, primarily the nuclei of the solitary tract within the reticular formation. The only visceroafferent system not to project directly to the insula is the olfactory system. The primary cortical field representing olfaction is not located within the neocortex but in a part of the allocortex called the rhinencepahlon. It is located near the basal forebrain and is especially distinguished by its direct inputs from the olfactory bulb, which are not relayed within the thalamus (Figure 7).

Although the cerebral hemispheres appear identical to the naked eye, they are actually involved in different processing strategies. The so-called dominant hemisphere (left hemisphere in most humans) processes information in a sequential fashion and is therefore related to analytical functions like speech-processing, logical and mathematical thinking. The other (right in most humans) hemisphere processes in a more

Figure 7 Overview of the cortical projection of the sensory pathways. http://faculty.pasadena.edu/dkwon/chap10_A/chap%2010_A%20accessible_files/textmostly/slide6.html.

holistic fashion and is therefore relevant for creativity, music- and art-processing, spatial orientation, personality, and facial recognition. The extent to which the cerebral hemispheres function differently from each other is called lateralization and is found to the greatest degree in humans, within whom it has also been suggested to be correlated positively with cognitive functions (Lebel and Beaulieu, 2009).

In order to function as a whole, especially with regard to higher-order processing, various areas within the cerebral cortex need to be interconnected, and the cortex additionally needs to communicate with noncortical and noncerebral brain areas. Those fiber tracts connecting similar areas of opposite hemispheres as called commissural fibers. The largest commissure in the brain is the corpus callosum, connecting major parts of both cerebral hemispheres. Although other cerebral commissures exist, the most important ones to mention are the anterior cerebral commissure, which connects both temporal lobes (including the amygdalae), and the fornical commissure, which connects both hippocampal formations.

Fibers connecting different areas within the same cerebral hemisphere are called association-fibers and can be divided into long and short association-fibers. The first span great lengths by connecting, e.g., the frontal with the occipital (superior longitudinal fasciculus) or temporal (arcuate and uncinate fasciculi) or the occipital with the temporal lobe (inferior longitudinal fasciculus). Another important long association tract is the cingulum, which lies within the eponymous cingulate gyrus and connects it with the hippocampal formation. Short association-fibers, on the other hand, are also called cerebral arcuate fibers and only connect adjacent gyri. The major body of long cerebral association-fibers is macroscopically referred to as the external capsule, whereby the arcuate fibers of the insula are analogously also called the extreme capsule.

Finally, fibers connecting the cerebral cortex with subcortical areas of the CNS, whereof the internal capsule is the largest and most prominent, are called projection-fibers. The internal capsule begins or terminates (depending on fiber direction) in the cerebral cortices and comprises many fiber tracts; inter alia, the corona radiata (between cortex and thalamus), the pyramidal tract (between the precentral gyrus and the anterior horn of the spinal cord), the spinothalamic tracts, and the medial as well as trigeminal lemnisci (connecting the epicritic nuclei of the brainstem with the thalamus). During its passage of the basal cerebral nuclei (aka basal ganglia), it lies between the caudate and lentiform nuclei. During ontogeny it displaces the caudate from the putamen, wherefore the resulting structure is called the striatum, due to small gray matter connections still remaining between the two nuclei. The part of the internal capsule near the apex of the lentiform nucleus exhibits a twisting, wherefore the various axons are in extremely close proximity to each other. This is of great clinical relevance, since lesions within this so-called genu of the internal capsules (e.g., through infarction) have dire consequences for the patient. After its passage of the basal cerebral nuclei and the diencephalon, the internal capsule lies at the anterior aspect of the midbrain and is here called the cerebral crura or (together with

parts of the midbrain tegmentum) the cerebral peduncles. The corticospinal or pyramidal tract can also be seen on the anterior aspect of the medulla oblongata where it forms the pyramids.

A second important projection-fiber is the fornix. It connects the hippocampal formation in the temporal lobe with the septal area of the basal forebrain and the mammillary bodies of the hypothalamus and is involved in memory consolidation as part of the extended neuronal circuit of Papez as formulated by Paul MacLean.

Cortical Plasticity and Change

Although the nervous system is generally known for its enormous capacity for synaptic plasticity and change, both cortical regions of the brain (i.e., the cerebellar and cerebral cortices) are exceptional in this respect. While often attributed to the works of Donald Hebb and the group surrounding Per Andersen (including Terje Lomo, who was the first to show long-term potentiation in the rabbit hippocampus during his doctoral work in the Andersen lab), the notion of synaptic plasticity as the basis of learning and memory was actually introduced by Santiago Ramón y Cajal during his Croonian lecture in 1894.

Two major factors are of relevance for the change in synaptic transmission and morphology, namely afferent input and exercise or repetition. The first factor has been shown repeatedly by, e.g., Witt-Lajeunesse (2001) and Comeau et al. (2010), who showed that rodents presented with a diversified and rich array of stimuli (so-called complex housing) show significantly higher levels of synaptic plasticity as well as resilience to neural lesions as compared with animals housed in a less stimulating environment. Especially the findings of the latter group are of special noteworthiness, since they were the first to show that stimulating sensory inputs not only lead to plasticity in primary sensory areas of the cortex but also in areas upstream regarding higher cortical functions; i.e., the prefrontal cortex. The adverse effect was shown, e.g., by Plank et al. (2011) in patients suffering from retinal dystrophy, who exhibited specific atrophy of the primary visual cortex.

The effects of exercise on synaptic plasticity have also been shown by numerous researchers. The aforementioned study by Plank et al. (2011) found a linear relationship between the fixation-stability of the eyes on a target and the gray matter volume of the frontal eye-field. Similarly, Draganski et al. (2004) recruited 24 healthy volunteers and instructed 12 of these in juggling, while the others served as controls. After 3 months, brain scans of the juggling-group showed significant increases in gray matter volume both compared with baseline and to controls. These changes began to normalize after another 3 months during which participants were instructed to no longer practice juggling, whereby gray matter volumes were still higher than at baseline, as the capability for juggling was not completely lost.

When comparing the volume of the posterior hippocampus, Woollett and Maguire (2011) found significant increases in participants who had successfully acquired the knowledge of the layout of Central London as part of their training to become a taxi-driver. With no initial differences between aspiring taxi-drivers and controls, several years later the authors found significant increases in gray matter volume in those participants that had successfully passed their examination; both compared with controls and to participants who had not acquired a license as a taxi-driver. The latter group had – on average – spent only half the time studying compared with the successful participants and did not differ significantly from controls regarding their change in the posterior hippocampal volume.

Finally, a number of studies both in humans and nonhuman primates show that either loss or the intense sensory stimulation of body parts lead to redistribution of corresponding areas of the cerebral cortex, a process referred to as recruitment or cortical remapping. Those areas that no longer receive sensory input are taken over by adjacent cortical fields, while vice versa cortex areas receiving increased sensory input enlarge and take over regions irrespective of whether they initially were related to other areas of the body.

Differential Lamination of the Cerebral Iso- and Allocortices

Isocortex

As mentioned in the introductory paragraph, the isocortex (corresponding to the neocortex) is generally comprised of six layers, while the allocortex (corresponding to the archi- and paleocortices) is mostly three-layered. The borders between one cortex type and the other are usually not sharp but made up of transition zones that can be subsumed under the name mesocortices.

The basic layout of the isocortex begins with an apical glial layer, the external glial limiting membrane, which borders on the outer isocortical layer, named the molecular layer due to its sparse neuronal population. The molecular layer entails a fiber plexus (plexus tangentialis or Exner-band) and is heavily involved in cortical ontogeny. As the first layer to develop from the subventricular zone, it encompasses a number of neurons (Cajal-Retzius cells) that attract subsequently developing neurons while simultaneously producing proteins that inhibit neuronal migration. As a consequence, the following layers of the isocortex develop inversely; i.e., sixth-layer neurons migrate until they reach the border of the molecular layer, followed by fifth layer neurons, that migrate through the anlage of layer VI, again until reaching the border of the molecular layer. This process subsequently is repeated by neurons forming layers IV, III, and finally II. After the termination of the migration of second-layer neurons, Cajal-Retzius cells go into apoptosis (programmed cell death), leading to the final low neuronal density in the fully developed isocortical molecular layer (**Figure 8**).

The innermost layer of the isocortex, the multiform layer, is made up of various different neuronal types and borders on the cortical white matter. Between the molecular and multiform layers (I and VI, respectively) two neurons typical to the cerebral cortices, namely pyramidal and spiny stellate or granule cells, form distinctive layers that are eponymously named. From the molecular layer downward these are the external granular (II), external pyramidal (III), internal granular (IV), and internal pyramidal (V) layers. Similar to the molecular layer, the layers III, IV, and V also encompass tangentially oriented fiber plexus, whereof the outer band of

Figure 8 Neuronal migration during ontogeny of the human neocortex.

Baillarger in layer IV is especially noteworthy due to its historical connotations. Within the primary visual cortex it is of such prominence that it can be seen with the naked eye and was so seen by the medical student Gennari, wherefore it is also called the stria of Gennari within the analogously named striated area of the occipital cortex (in some texts, the stria of Gennari is also referred to as the stria of Vicq-d'Azyr) (Figure 9).

The functions of pyramidal cells and spiny stellate cells within the isocortex are discrete, whereby pyramidal cells give rise to efferent axons and spiny stellate cells represent the termination points of afferent fibers. The external layers (II and III) are mainly involved in corticocortical connections, whereas the internal layers (IV and V) receive or respectively give rise to projection fibers. Due to these functional differences, primary sensory cortical fields lack a clearly distinguishable layer V, but exhibit a very prominent layer VI, and are therefore called granular cortices. Primarily efferent cortical fields (most importantly the precentral gyrus) have a large layer V but not clearly distinguishable layer VI and are therefore called agranular cortices. It therefore becomes clear that, although histologically named isocortex, the lamination within the neocortex is not equal in all cortical fields. This differential lamination lead Korbinian Brodmann to propose over 50 individual cortical fields, many of which have since been corroborated by more modern methods (Figure 10).

Allocortex

Although phylogenetically older and three-layered, the same basic principles as mentioned for the isocortex apply to the allocortex. Since a detailed coverage of the entire allocortex would exceed the scope of this article, the lamination of the allocortex shall only be illustrated exemplarily for the two gyri comprising the retrocommissural hippocampus (or proper hippocampus). These gyri are the dentate gyrus and Ammon's horn. Unlike the isocortex, both of these gyri encompass only one fiber directional modality, making the basic connectivity of the proper hippocampus a one-way street. The dentate gyrus receives input (primarily from the entorhinal cortices) and therefore exhibits a prominent granular layer, surrounded by a molecular and a multiform or plexiform layer, but no pyramidal layer. Ammon's horn, on the other hand, is the efferent gyrus of the proper hippocampus and therefore has a pyramidal but no granular layer. Due to ontogeny, both gyri of the proper hippocampus are inversely positioned, wherefore their respective white matter tracts lay apically rather than

Figure 9 Cytoarchitecture of the neocortex (in three staining-methods). Modified by Grant from Strandring, Gray's Anatomy, 39th ed.; figure 22.10.

away from the surface. The white matter tract conveying inputs from the entorhinal cortices to the dentate gyrus is the perforant tract and lies within the molecular layer of Ammon's horn, the white tract of which is the alveus bordering on the cerebral ventricle. The molecular layer of Ammon's horn can be divided further, wherefore the layer encompassing the perforant tract is referred to as the lacunose molecular layer. It is separated from the pyramidal layer by the radiatum layer, which holds axon collaterals – the Schaffer-collaterals – connecting pyramidal cells from different sectors of Ammon's horn (namely CA3 to CA1; CA standing for Cornu ammonis, which is Latin for Ammon's horn). The final layer of the proper hippocampus, between the pyramidal layer and the alveus, is the oriens layer. Within the sector CA3, which lies near the dentate gyrus, a third layer can be distinguished with the molecular layer of Ammon's horn (also called Ammon's horn). This layer carries unmyelinated axons from the dentate gyrus' granule cells, that contact the CA3-pyramidal cells. It is therefore only present in CA3 and not stainable with classical techniques (e.g., Kluver-Barrera or Weigert), wherefore it is called the lucid layer (Figure 11).

Interactions of the Cerebral Cortex with the Thalamus

A number of misconceptions exist regarding thalamocortical and corticothalamic interactions. First, it is important to distinguish between two major portions of the thalamus, namely the dorsal (i.e., the thalamus proper) and the ventral thalamus. While the dorsal thalamus is usually referred to only as 'thalamus,' the ventral thalamus (not to be confused with the ventral nuclear group of the (dorsal) thalamus) is often subsumed under mainly the basal cerebral nuclei. It consists, inter alia, of the subthalamic nucleus, the external and internal pallidum, and the reticular thalamic nucleus, whereby only the latter shall by explained functionally here.

The main function of the ventral thalamus is to regulate the activity of the dorsal thalamus. This becomes inherently clear when taking into account that connections between the dorsal thalamus and the cerebral cortex are generally reciprocal; i.e., excitation or inhibition of the cortex by the thalamus in turn leads to respective excitation or inhibition of the thalamus by the cortex and vice versa. The existence of a controlling structure is therefore necessary and is found especially in the reticular nucleus of the ventral thalamus. This structure is thalamotopically organized, surrounds the dorsal thalamus like a shell, and receives collaterals of all axons between the dorsal thalamus and the cerebral cortex. While these axons are usually excitatory in nature, the ensuing projections of the reticular nucleus have an inhibiting effect of the respective nuclei of the dorsal thalamus (Figure 12).

Another misconception stems from the existence of functional subdivisions of the dorsal thalamus. It was long believed that the dorsal thalamus consisted of such regions involved in the relaying of information to the cerebral cortex and as such functioned as regulators of general cerebral activity. These regions were named the specific or corticothalamus and the unspecific or truncothalamus, respectively. The unspecific thalamus was considered an extension of the brain stem's ascending reticular activation systems and was, inter alia,

proposed by Eysenck as the neurobiological foundation of extraversion.

A number of studies from the early twenty-first century have, however, conclusively disproven this notion, wherefore neuroscientists now propose the distinction between isothalamus and allothalamus: While the allothalamus communicates primarily with the basal cerebral nuclei, the isothalamus interacts with the cerebral cortex. It has been shown that each and every isothalamic nucleus has both neurons that relay information to the thalamus (by projecting to the internal granular layer) as well as neurons that have slightly broader regions of cortical innervation, projecting into the molecular and multiform layers and being therefore believed to influence the way in which the cortex processes information relayed by the thalamic neurons projecting into layer IV.

Figure 12 Schematic illustration of the neuronal interaction between the dorsal thalamus and the cerebral cortex; role of the reticular nucleus; green indicates excitatory and red inhibitory projections.

There also exist isothalamic interneurons, wherefore it is believed that a number of corticocortical connections may actually not be direct but relayed through the dorsal thalamus. This mechanism additionally allows for control over thalamic activity by the cerebral cortex itself. This is also of major importance to thalamocortical function, as a major job of the thalamus is the regulation of cortical processing (see above). Here also misconceptions exist, as it is suggested that the thalamus 'decide' on the filtering of information. This is, however, not true, as the thalamus itself does not actually filter information out and also does not possess the necessary 'background information' to achieve this task (Figure 13).

This can be illustrated for selective information processing by example of the so-called 'Cocktail-Party effect': An individual following a specific conversation during a party will filter out all other conversations going on within earshot. Hearing his or her name (or any other personally salient word) used within any of these other conversations, however, will lead to an immediate relocation of attention to the previously ignored conversation. This example clearly illustrates both the function of corticothalamic connectivity as well as the impossibility of filtering solely on the thalamic level. First, the thalamus does not store information of this nature, wherefore it cannot 'interpret' its personal relevance as only the forebrain can. Second, the 'dropping' of one's own name is not anticipated and therefore occurs during a time when the conversation is supposedly still 'filtered out,' wherefore it is clear that it is in actuality not filtered out, but reaches the limbic areas of the cerebral cortex, if only processed differently there compared with the conversation that had been followed to this point. Third and finally, the immediate relocation of attention – in other words, the nature of cortical processing of received information – shows that connections exist between different cortical regions via the thalamus, in this example from (probably) the prefrontal and association cortices to the primary and secondary auditory cortices.

Figure 13 Schematic illustration of thalamo-cortical and cortico-thalamo-cortical projections.

In conclusion, the thalamus is fundamentally involved in the function of the cerebral cortex as it not only relays information to layer IV spiny stellate cells; it additionally protects the cerebral cortex from overload (a concept that actually exists on the neuronal level in so-called neuronal excitotoxicity) through the ventral thalamus, especially the reticular nucleus. Finally, it is inherently relevant for the cortex' own control of information processing through the isothalamus as outlined above.
